Skimming flow of the rough stepped chute (Configuration $\mathrm{A}, \mathrm{d}_{\mathrm{C}} / \mathrm{h}=1.3, \mathrm{Re}=5.8 \mathrm{E}+5$ )

#### Abstract

On a stepped spillway at large flows, the waters skim over the pseudo-bottom formed by the step edges with very strong recirculation vortices in the step cavities. The effects of step roughness on the flow properties are little known despite the practical relevance : e.g., gabion stepped chutes, unprotected roller compacted concrete spillways, damaged concrete steps on older structures. In the present study, the effect of step roughness was investigated systematically in a new series of experiments. The work was performed in a large size laboratory facility, with step height of 0.10 m , step length of 0.25 m and chute width of 1 m , based upon an undistorted Froude similitude. Four configurations were thoroughly tested with identical flow conditions : a smooth stepped chute, and three configurations with rough step faces. The latters were achieved by placing rough screens on the step faces : i.e., on the vertical faces only (Config. B), on the horizontal step faces only (Config. C) and on both vertical and horizontal step faces (Config. A). Detailed air-water flow measurements were performed with a dual-tip phase detection probe (sensor size: 0.025 mm ). Basic results included the vertical distributions of air concentration, bubble count rate, air-water velocity, turbulence level, and the air and water chord size distributions at each sampling point. The results showed some similarities between all four stepped configurations. Three basic flow regimes were observed, and the flow conditions at the change from one flow regime to another were identical for all four geometries. In skimming flows, visual observations showed that the step roughness affected the recirculation patterns in the step cavities. For the roughest configuration A, clear-water recirculation regions were observed downstream of the inception point of air entrainment. Seepage was also observed through the rough screens. At a macroscopic level, the effects of step roughness were two-fold. The location of the inception point of free-surface aeration was further downstream than for a smooth stepped chute for an identical flow rate. In turn the residual energy at the downstream end of the chute was greater on the rough stepped chute. At a microscopic level, the experimental results showed consistently several trends. The void fraction distribution results were very close for all stepped configurations, although there seemed to be slightly less entrained air in the rough stepped chute flows. Bubble count rate distributions indicated systematically lesser bubble count rates in the rough stepped chute flows. At step edges, the rough stepped chute flows were faster than smooth chute flows for a given flow rate and dimensionless location from the inception point of free-surface aeration. This was associated with lower turbulence intensities in rough stepped channel flows. A detailed analysis of air and water chord size distributions showed that, at each sampling location, the distributions of air and water chords were broad and spanned over two to three orders of magnitude. In the bubbly flow region (C $<0.3$ ), the probability distribution functions of air chord sizes followed closely a log-normal law for all investigated configurations and flow conditions.

## NOTATION

The following symbols are used in this report :

| A | flow cross-section area ( $\mathrm{m}^{2}$ ); |
| :---: | :---: |
| a | specific interface area $\left(\mathrm{m}^{-1}\right)$ defined as the air-water surface area per unit volume of air and water; |
| $\mathrm{a}_{\text {mean }}$ | mean interface area $\left(\mathrm{m}^{-1}\right)$ in a cross-section of fluid normal to the flow direction : $\mathrm{a}_{\text {mean }}=\frac{1}{\mathrm{Y}_{90}} * \int_{0}^{\mathrm{Y}_{90}} \mathrm{a} * \mathrm{dy}$ |
| C | air concentration defined as the volume of air per unit volume; (Note : it is also called void fraction); |
| $\mathrm{C}_{\text {mean }}$ ch | depth averaged air concentration defined as : $\left(1-\mathrm{C}_{\text {mean }}\right) * \mathrm{Y}_{90}=\mathrm{d}$; chord size (m); |
| $\mathrm{D}_{\mathrm{H}}$ | hydraulic diameter (m) defined as : $\mathrm{D}_{\mathrm{H}}=4 * \frac{\mathrm{~A}_{\mathrm{W}}}{\mathrm{P}_{\mathrm{W}}}$; |
|  | $\left(D_{H}=\frac{4 * d^{*} W}{W+2 * d}\right.$ for a rectangular channel $)$ |
| d | characteristic depth (m) defined as : $\mathrm{d}=\int_{0}^{\mathrm{Y}_{90}}(1-\mathrm{C}) * \mathrm{dy}$; |
| $\mathrm{d}_{\mathrm{ab}}$ | air bubble size (m); |
| $\mathrm{d}_{\mathrm{wd}}$ | water droplet size (m); |
| $\mathrm{d}_{\mathrm{c}}$ | critical flow depth (m); for a rectangular channel : $d_{c}=\sqrt[3]{q_{w}{ }^{2 / g}}$; |
| $\begin{aligned} & \mathrm{d}_{\text {crest }} \\ & \mathrm{d}_{50} \end{aligned}$ | flow depth (m) measured above the weir crest; median grain size ( m ); |
| E | specific energy (m); |
| F | bubble count rate ( Hz ) : i.e., number of bubbles impacting a probe per second; |
| $\mathrm{F}_{\text {max }}$ | maximum bubble count rate ( Hz ) in a cross-section; |
| $\mathrm{F}_{\text {scan }}$ | scanning rate (Hz); |
| Fr | Froude number; |
| F* | Froude number defined in terms of the roughness height : |
|  | 1- $\mathrm{F} *=\mathrm{q}_{\mathrm{W}} / \sqrt{\mathrm{g} * \sin \theta *\left(\mathrm{k}_{\mathrm{S}}\right)^{3}}$ for smooth chute flow; <br> 2- $F *=q_{W} / \sqrt{g * \sin \theta * k_{S}{ }^{3}}$ for skimming flow on stepped chute; |
| f | Darcy-Weisbach friction factor; |
| g | gravity constant (m/s ${ }^{2}$ ) : $\mathrm{g}=9.80 \mathrm{~m} / \mathrm{s}^{2}$ in Brisbane, Australia; |
| H | total head (m); |
| $\mathrm{H}_{\text {max }}$ | maximum head available (m) using the spillway toe as datum; |
| $\mathrm{H}_{\text {res }}$ | residual head (m) at the downstream end of the spillway, using the spillway toe as datum : $\mathrm{H}_{\text {res }}=\mathrm{H}_{\text {max }}-\Delta \mathrm{H}$; |
| $\mathrm{H}_{1}$ | upstream total head (m) measured from the inflow channel invert; |
| h | height of steps (m) (measured vertically); |
| k | rough screen height (m); herein $\mathrm{k}=8 \mathrm{~mm}$; |
| $\mathrm{k}_{\text {S }}$ | step dimension (m) measured normal to the flow direction : $\mathrm{k}_{\mathrm{S}}=\mathrm{h} * \cos \theta$; |
| $\mathrm{k}_{\text {S }}{ }^{\prime}$ | equivalent sand roughness height ( m ) of the step surface : i.e., surface (skin) roughness height; |
| L | spillway chute length (m); |
| $\mathrm{L}_{\text {cav }}$ | cavity length (m); |

| $\mathrm{L}_{\text {I }}$ | distance (m) from the start of growth of boundary layer to the inception point of air entrainment; |
| :---: | :---: |
| $\mathrm{L}_{\mathrm{r}}$ | ratio of prototype to model dimensions; |
| , | horizontal length of steps (m) (measured perpendicular to the vertical direction); $\mathrm{g} * \mu_{\mathrm{w}}^{4}$ |
| Mo | Morton number defined as: $\mathrm{Mo}=\frac{\rho_{\mathrm{W}} * \sigma^{3}}{}$; |
| $\mathrm{n}_{\text {Manning }}$ | Gauckler-Manning coefficient ( $\mathrm{s} / \mathrm{m}^{1 / 3}$ ); |
| $\mathrm{P}_{\mathrm{W}}$ | wetted perimeter (m); |
| Q | discharge ( $\mathrm{m}^{3 / \mathrm{s}}$ ); |
| $\mathrm{Q}_{\mathrm{W}}$ | water discharge ( $\mathrm{m}^{3} / \mathrm{s}$ ); |
| q | discharge per unit width ( $\mathrm{m}^{2} / \mathrm{s}$ ); |
| $\mathrm{q}_{\mathrm{w}}$ | water discharge per unit width ( $\mathrm{m}^{2} / \mathrm{s}$ ); |
| Re | Reynolds number defined in terms of the depth-averaged flow velocity and hydraulic diameter : $\operatorname{Re}=\rho_{\mathrm{w}} * \mathrm{U}_{\mathrm{w}} * \mathrm{D}_{\mathrm{H}} / \mu_{\mathrm{w}}$; |
| $\mathrm{R}_{\text {max }}$ | maximum cross-correlation function value; |
| $\mathrm{R}_{\mathrm{xx}}$ | normalised auto-correlation function; |
| $\mathrm{R}_{\mathrm{xy}}$ | normalised cross-correlation function; |
| $\mathrm{S}_{\mathrm{f}}$ | friction slope : $\mathrm{S}_{\mathrm{f}}=-\partial \mathrm{H} / \partial \mathrm{x}$; |
| $\mathrm{S}_{\mathrm{o}}$ | bed slope : $\mathrm{S}_{\mathrm{O}}=\sin \theta$; |
| T | characteristic time (s) for which the cross-correlation function is maximum; |
| Tu | turbulence intensity defined as : $\mathrm{Tu}=\mathrm{u}^{\prime} / \mathrm{V}$; |
| t | time (s); |
|  | Y90 |
| $\mathrm{U}_{\mathrm{W}}$ | equivalent clear-water flow velocity $(\mathrm{m} / \mathrm{s}): \mathrm{U}_{\mathrm{W}}=\mathrm{q}_{\mathrm{w}} / \mathrm{d}=\mathrm{q}_{\mathrm{w}} / \int_{0}(1-\mathrm{C}) *$ dy ; |
| $\mathrm{u}^{\prime}$ | root mean square of longitudinal component of turbulent velocity ( $\mathrm{m} / \mathrm{s}$ ); |
| V | velocity ( $\mathrm{m} / \mathrm{s}$ ); |
| $\mathrm{V}_{\mathrm{b}}$ | interfacial velocity ( $\mathrm{m} / \mathrm{s}$ ); |
| $\mathrm{V}_{\mathrm{c}}$ | critical flow velocity ( $\mathrm{m} / \mathrm{s}$ ); for a rectangular channel : $\mathrm{V}_{\mathrm{c}}=\sqrt[3]{\mathrm{g} * \mathrm{q}_{\mathrm{W}}}$; |
| $\mathrm{V}_{90}$ | characteristic velocity ( $\mathrm{m} / \mathrm{s}$ ) where the air concentration is $90 \%$; |
| v' | root mean square of lateral component of turbulent velocity ( $\mathrm{m} / \mathrm{s}$ ); |
| W | channel width (m); |
| $\mathrm{X}_{0}$ | dimensionless distance from the upstream step edge: $\mathrm{X}_{\mathrm{O}}=\mathrm{x}^{\prime} / L_{c a v}$; |
| x | longitudinal/streamwise distance (m); |
| x' | streamwise distance (m) from the upstream step edge; |
| Y90 | characteristic depth (m) where the air concentration is $90 \%$; |
| y | distance ( m ) from the pseudo-bottom (formed by the step edges) measured perpendicular to the flow direction; |

## Greek symbols

$\Delta \mathrm{T} \quad$ time scale $(\mathrm{m})$ satisfying: $\mathrm{R}_{\mathrm{xy}}(\mathrm{T}+\Delta \mathrm{T})=\mathrm{R}_{\text {max }} / 2$;
$\Delta t \quad$ characteristic time (s) for which the normalised autocorrelation function equals 0.5 ;
$\Delta \mathrm{x} \quad$ streamwise distance ( m ) between the probe sensors;
$\Delta z \quad$ weir crest height (m) above the intake channel invert;
$\mu \quad$ dynamic viscosity ( $\mathrm{N} . \mathrm{s} / \mathrm{m}^{2}$ );
$v \quad$ kinematic viscosity $\left(\mathrm{m}^{2} / \mathrm{s}\right)$;
$\pi \quad \pi=3.141592653589793238462643 \ldots$;
$\theta \quad$ angle between the pseudo-bottom formed by the step edges and the horizontal;
$\rho \quad$ density $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$;
$\sigma \quad$ surface tension between air and water ( $\mathrm{N} / \mathrm{m}$ );
$\tau \quad$ shear stress (Pa);
$\tau_{\mathrm{o}} \quad$ boundary shear stress ( Pa );

## 1. INTRODUCTION

### 1.1 PRESENTATION

Stepped channels have been used for more than 3,500 years. The Greek engineers were possibly the first to design an overflow stepped spillway : i.e., an overflow stepped weir in Akarnania built around BC 1300 (CHANSON 2001-2002). Figure 1-1 presents several stepped chute designs. The stepped design increases the rate of energy dissipation on the chute (i.e. above the steps) and reduces the size of the downstream energy dissipator. During the last three decades, research in the hydraulics of stepped spillways has been very active (CHANSON 1995a,2001, OHTSU and YASUDA 1998). For a given stepped chute, water flows as a succession of free-falling nappes (nappe flow regime) at small discharges (Fig. 1-1A). For an intermediate range of flow rates, a transition flow regime is observed (Fig. 1-1C). Most prototype spillways operate at large discharges per unit width (i.e. skimming flow regime) for which the waters skim as a coherent stream over the pseudo-bottom formed by step edges (Fig. 1-1D). Skimming flows are characterised by verysignificant form losses and momentum transfer from the main stream to the recirculation zones (e.g. RAJARATNAM 1990, OHTSU and YASUDA 1997, CHANSON et al. 2002). There is an obvious analogy with skimming flows past large elements and boundary layer flows past d-type roughness: e.g., KNIGHT and MACDONALD (1979), DJENIDI et al. (1999).

Stepped chute hydraulics is not simple because of different flow regimes, but importantly because of strong flow aeration, very-strong turbulence, and interactions between entrained air and turbulence (CHANSON and TOOMBES 2002a,b,2003, YASUDA and CHANSON 2003). Recently several studies investigated the effects of macro-roughness and turbulence manipulation on skimming flow properties (ANDRE et al. 2004, CHANSON and GONZALEZ 2004, GONZALEZ and CHANSON 2004a,2005, KOKPINAR 2004). Surprisingly, the effects of step roughness on the flow properties remain unknown, despite the practical relevance : e.g., gabion stepped chutes, unprotected roller compacted concrete chutes, damaged concrete steps on older structures (Fig. 12). PEYRAS et al. $(1991,1992)$ studied experimentally the hydraulics of gabion stepped weirs. KELLS $(1993,1995)$ discussed the interactions between of seepage and free-surface flows, while CHANSON $(1995 a, 2001)$ reviewed basic design considerations.
It is the purpose of this study to study thoroughly the effects of step roughness in skimming flows on a stepped chute. New measurements were conducted in a large-size facility ( $\theta=22^{\circ}, \mathrm{h}=0.1 \mathrm{~m}$ ) with two step conditions (smooth and rough) and three types of step roughness. Detailed air-water flow properties were measured systematically for several flow rates. The results provide a new understanding of the effects of step face roughness on the flow characteristics of skimming flows.

Fig. 1-1 - Photographs of stepped chutes and spillways
(A) Nappe flow at Lake Wilde dam spillway (Maryland, USA) during a 1-year return period flood on 23 March 2005 (Courtesy of Christopher R. GOODELL, WEST Consultants)

(B) Overflow on the Opuha dam stepped spillway (Courtesy of Tonkin and Taylor, NZ) - Dam height: 47 m , completion: 1999 , spillway slope: $\theta=26.6^{\circ}(1 \mathrm{~V}: 2 \mathrm{H})$, design flow: $315 \mathrm{~m}^{3} / \mathrm{s}, \mathrm{h}=1 \mathrm{~m}$, $1=2 \mathrm{~m}$

(C) Spray, splashing and waves in transition flow on a steep stepped chute downstream of a culvert near Sonson, Columbia (Courtesy of Sergio LLANO, International Institute for Infrastructural, Hydraulic and Environmental Engineer) - Original design operating with $\mathrm{Q}=0.8 \mathrm{~m}^{3} / \mathrm{s}$, chute length: 36.3 m , width: $1.5 \mathrm{~m}, \mathrm{~h}=1.5 \mathrm{~m}, \mathrm{l}=2$ to 3 m - The chute step design was subsequently modified to avert transition flow regime operation

(D) Skimming flow on the Volymia experimental earth dam ( 20 m high) spillway in the Magadan region (Siberia) (Courtesy of Prof. Yuri PRAVDIVETS, Moscow Institute of Civil Engineers, Russia) - For 15 years, the stepped spillway has been discharging ice and water from early spring to late fall as an un-gated overflow - The chute slope is $1 \mathrm{~V}: 2 \mathrm{H}$, ending with a ski jump (PRAVDIVETS 1992, CHANSON 2001)

Fig. 1-2 - Photographs of rough stepped chutes
(A) Gabion stepped weir at Robina, Gold Coast (Australia) on 2 Apr. 1997, shortly after completion - Stepped weir characteristics : $\mathrm{h}=0.6 \mathrm{~m}, \mathrm{~W}=10.5 \mathrm{~m}$, Reno mattress construction

(B) Gabion stepped weir at Guaribraba, Capo Grande Brazil (Courtesy of Officine Maccaferri) Note the seepage flow, the absence of overflow and the increasing seepage with downstream distance from the crest

(C) Nappe flow at Duralie NSW (Australia on 21 October 2004) (Courtesy of Tony MARSZALEK and Gilbert \& Associates, Brisbane) - Slope : $1 \mathrm{~V}: 5 \mathrm{H}, \mathrm{h}=0.5 \mathrm{~m}$, gabion/reno mattresses construction $\left(\mathrm{d}_{50}=150 \mathrm{~mm}\right)$, completed in 2004

### 1.2 DIMENSIONAL ANALYSIS AND SIMILITUDE

A dominant characteristic of stepped chute flows is the strong flow aeration ('white waters') clearly seen in prototype and laboratory. Theoretical analysis (and numerical study) is limited considering the large number of relevant equations : i.e., three basic equations per phase plus a phase transfer equation. Experimental investigations are also difficult but recent advances in air-water flow instrumentation brought new measuring systems enabling successful experiments (e.g. CHANSON 2002, CHANSON and TOMBES 2002a). Traditionally model studies are performed with geometrically similar models and the geometric scaling ratio $L_{r}$ is defined as the ratio of prototype to model dimensions. Laboratory studies of air-water flows require however the selection of an adequate similitude.
The relevant parameters needed for any dimensional analysis include the fluid properties and physical constants, the channel geometry and inflow conditions, the air-water flow properties including the entrained air bubble characteristics, and the geometry of the steps (CHANSON and GONZALEZ 2005). Considering a skimming flow down a stepped chute with flat horizontal steps at uniform equilibrium and for a prismatic rectangular channel, a complete dimensional analysis yields a relationship between the local air-water flow properties, and the fluid properties, physical constants, flow conditions and step geometry :

$$
\begin{equation*}
\mathrm{C}, \frac{\mathrm{~V}}{\sqrt{\mathrm{~g} * \mathrm{~d}}}, \frac{\mathrm{u}^{\prime}}{\mathrm{V}}, \frac{\mathrm{~d}_{\mathrm{ab}}}{\mathrm{~d}}, \ldots=\mathrm{F}_{1}\left(\frac{\mathrm{x}}{\mathrm{~d}} ; \frac{\mathrm{y}}{\mathrm{~d}} ; \frac{\mathrm{q}_{\mathrm{w}}}{\left.\left.\sqrt{\mathrm{~g}^{* \mathrm{~d}^{3}}} ; \rho_{\mathrm{w}} * \frac{\mathrm{q}_{\mathrm{w}}}{\mu_{\mathrm{W}}} ; \frac{\mathrm{g} * \mu_{\mathrm{W}}^{4}}{\rho_{\mathrm{W}}^{*} \sigma^{3}} ; \frac{\mathrm{d}}{\mathrm{~h}} ; \frac{\mathrm{W}}{\mathrm{~h}} ; \theta ; \frac{\mathrm{k}_{\mathrm{s}}^{\prime}}{\mathrm{h}}\right) .{ }^{\prime}\right) .}\right. \tag{1-1}
\end{equation*}
$$

where C is the local void fraction, V is the local velocity, g is the gravity acceleration, d is the equivalent water depth at uniform equilibrium, $u^{\prime}$ is a characteristic turbulent velocity, $d_{a b}$ is a characteristic size of entrained bubble, x is the coordinate in the flow direction measured from a step edge, y is the distance normal from the pseudo-bottom formed by the step edges, $\mathrm{q}_{\mathrm{w}}$ is the water discharge per unit width, $\rho_{\mathrm{W}}$ and $\mu_{\mathrm{w}}$ are the water density and dynamic viscosity
respectively, $\sigma$ is the surface tension between air and water, W is the chute width, h is the step height, $\theta$ is the angle between the pseudo-bottom and the horizontal, and $\mathrm{k}_{\mathrm{s}}{ }^{\prime}$ is the equivalent sand roughness height of the step surface (Fig. 1-3). In Equation (1-1), the characteristic length scale is taken as the equivalent clear water depth defined as :

$$
\begin{equation*}
d=\int_{\mathrm{y}=0}^{\mathrm{y}=\mathrm{Y}_{90}}(1-\mathrm{C}) * \mathrm{dy} \tag{1-2}
\end{equation*}
$$

where $\mathrm{Y}_{90}$ is the depth where $\mathrm{C}=0.9$. In the following sections, alternate characteristic length scales may be introduced in some places whenever appropriate, including the critical flow depth (Section 3), the step roughness $\mathrm{k}_{\mathrm{S}}=\mathrm{h}^{*} \cos \theta$ (Eq. (3-7)) or the step cavity length $\mathrm{L}_{\mathrm{cav}}=\sqrt{\mathrm{h}^{2}+1^{2}}$ (Section 4).
In Equation (1-1) right handside, the 3rd, 4th and 5th dimensionless terms are Froude, Reynolds and Morton numbers respectively, and the last four terms characterise the step cavity shape and the skin friction effects on the cavity wall. Note that compressibility of high-velocity air-water flow may be an important issue relevant to the design of spillways. A re-analysis of existing model and prototype data showed that transonic and supersonic flow conditions were achieved in a number of studies (CHANSON 1997, 2004c), but the results implied that, in free-surface flows, compressibility effects had little impact neither on the air bubble diffusion process nor on the mixing layer characteristics. Hence compressibility effects are not considered herein.
Any combination of dimensionless numbers is also dimensionless and may replace a dimensionless number. In particular, one parameter among the Froude, Reynolds and Weber numbers may be replaced by the Morton number $\operatorname{Mo}=\left(\mathrm{g}^{*} \mu_{\mathrm{w}}{ }^{4}\right) /\left(\rho_{\mathrm{w}}{ }^{*} \sigma^{3}\right)$ which is an invariant of the same fluids are used in model and prototype. In Equation (1-1), the Weber number was replaced by the Morton number.
Further simplifications may be derived by considering the depth-averaged air-water flow properties: i.e., the one-dimensional air-water flow properties. For a skimming flow at uniform equilibrium, Equations (1-1) yields :

$$
\begin{equation*}
\mathrm{F}_{2}\left(\frac{\mathrm{U}_{\mathrm{w}}}{\sqrt{\mathrm{~g} * \mathrm{~d}}} ; \rho_{\mathrm{W}} \frac{\mathrm{U}_{\mathrm{W}}^{*} \mathrm{~d}}{\mu_{\mathrm{W}}} ; \frac{\mathrm{g} * \mu_{\mathrm{w}}^{4}}{\rho_{\mathrm{w}}^{*} \sigma^{3}} ; \mathrm{C}_{\text {mean }} ; \frac{\mathrm{d}}{\mathrm{~h}} ; \frac{\mathrm{W}}{\mathrm{~h}} ; \theta ; \frac{\mathrm{k}_{\mathrm{s}}^{\prime}}{\mathrm{h}}\right)=0 \tag{1-3}
\end{equation*}
$$

where $\mathrm{U}_{\mathrm{W}}$ is the mean flow velocity $\left(\mathrm{U}_{\mathrm{W}}=\mathrm{q}_{\mathrm{w}} / \mathrm{d}\right)$ and $\mathrm{C}_{\text {mean }}$ is the depth-averaged void fraction:

$$
\begin{equation*}
C_{\text {mean }}=\frac{1}{\mathrm{Y}_{90}} * \int_{\mathrm{y}=0}^{\mathrm{y}=\mathrm{Y}_{90}} \mathrm{C} * d y \tag{1-4}
\end{equation*}
$$

In free-surface flows, most laboratory studies are based upon a Froude similitude (e.g. HENDERSON 1966, CHANSON 2004a). This is also the case with stepped spillway studies (e.g. BOES 2000, CHANSON and GONZALEZ 2005, TAKAHASHI et al. 2005). But cavity recirculation and momentum exchanges between cavity and stream flow are dominated by viscous effects suggesting the need for a Reynolds similitude, while the entrapment of air bubbles and the mechanisms of air bubble breakup and coalescence are dominated by surface tension effects implying the use of a Weber similitude. For geometrically-similar models, it is impossible to satisfy simultaneously Froude, Reynolds and Weber similarities unless $L_{r}=1$. In small size models ( $\mathrm{L}_{\mathrm{r}} \gg$ 1), the air entrainment process may be affected by significant scale effects. WOOD (1991) and CHANSON (1997) presented comprehensive reviews.
Despite very simplistic assumptions, Equation (1-1), and even Equation (1-3), demonstrate that true dynamic similarity of stepped chute flows is almost impossible to achieve with geometrically similar models, unless working at full-scale, because of the large number of relevant parameters. It is therefore important to clarify the ranges of flow conditions in which viscous and surface tension effects are negligible. Note that, usually, the same fluids (air and water) are used in model and
prototype, and the Morton number becomes an invariant.

## Discussion

Few studies tested systematically the validity of a Froude similitude on stepped chutes based upon a geometric similarity using the same fluids in model and prototype (see review by CHANSON 2004b, pp. 358-364). These were based upon a Froude similitude with undistorted geometric scale and sometimes two-dimensional models. BaCaRa (1991) described a systematic laboratory investigation of M'Bali dam spillway with model scales of $L_{r}=10,21.3,25$ and 42.7. No prototype test was conducted. For the smallest models $\left(\mathrm{L}_{\mathrm{r}}=25 \& 42.7\right)$, the flow resistance was improperly reproduced. CHANSON et al. (2002) re-analysed more than 38 model studies and 4 prototype investigations with channel slopes ranging from $5.7^{\circ}$ up to $55^{\circ}$, and with Reynolds numbers between $3 \mathrm{E}+4$ and $2 \mathrm{E}+8$. They concluded that physical modelling of flow resistance may be conducted based upon a Froude similitude if laboratory flow conditions satisfy $\mathrm{h}>0.020 \mathrm{~m}$ and $\operatorname{Re}$ $>1 \mathrm{E}+5$. They added that true similarity of air entrainment was achieved only for model scales $\mathrm{L}_{\mathrm{r}}<$ 10. However detailed studies of local air-water flow properties (BOES 2000, GONZALEZ and CHANSON 2004b, CHANSON and GONZALEZ 2005) yielded more stringent conditions suggesting the impossibility to achieve dynamic similarity, even in large-size models.
In the present study, a Froude similitude was used as for most open channel flow studies and past studies. However experiments were conducted in a large size facility operating at large Reynolds numbers. These conditions are representative of full-scale storm waterway and could be considered as $3: 1$ to $6: 1$ scale studies of a RCC stepped spillway with step height of 0.3 to 0.6 m . The purpose of the present study was to investigate systematically the effects of step face roughness $\mathrm{k}_{\mathrm{s}}{ }^{\prime}$ on skimming flow properties.

## 2. EXPERIMENTAL SETUP

### 2.1 PRESENTATION

New experiments were conducted in the Gordon McKAY Hydraulic Laboratory of the Department of Civil Engineering at the University of Queensland. The experimental channel was previously used by CHANSON and TOOMBES $(2001,2002 \mathrm{a}, 2003)$ and GONZALEZ (2005) with smooth step faces. Waters were supplied from a large feeding basin ( 1.5 m deep, surface area $6.8 \mathrm{~m} \times 4.8 \mathrm{~m}$ ) leading to a sidewall convergent with a 4.8:1 contraction ratio. The test section consisted of a broad-crested weir ( 1 m wide, 0.6 m long, with upstream rounded corner ( 0.057 m radius)) followed by ten identical steps ( $\mathrm{h}=0.1 \mathrm{~m}, \mathrm{l}=0.25 \mathrm{~m}$ ) made of marine ply (Fig. 2-1). Rough screens or triangular vanes could be installed on the steps (CHANSON and GONZALEZ 2004, GONZALEZ 2005, Present study). The stepped chute was 1 m wide with perspex sidewalls followed by a horizontal concrete-invert canal ending in a dissipation pit.
A pump controlled with an adjustable frequency AC motor drive delivered the flow rate, enabling an accurate discharge adjustment in a closed-circuit system. Clear-water flow depths were measured with a point gauge. The discharge was measured from the upstream head above crest ${ }^{1}$ ). Air-water flow properties were measured using a double-tip conductivity probe ( $\varnothing=0.025 \mathrm{~mm}$ ) designed at the University of Queensland. The probe sensors were aligned in the flow direction (Fig. 2-2). The leading tip had a small frontal area (i.e. $0.05 \mathrm{~mm}^{2}$ ) and the trailing tip was offset to avoid wake disturbance from the first tip. Tests showed the absence of wake disturbance during all experiments (CHANSON 1995b). Further discussion on the probe design is developed in Appendix A. An air bubble detector (UQ82.518) excited the probe and its output signal was scanned at 20 kHz per sensor for 20 seconds.
The translation of the probes in the direction normal to the channel invert was controlled by a fine adjustment travelling mechanism connected to a Mitutoyo ${ }^{\text {TM }}$ digimatic scale unit (Ref. No. 572503).

Flow visualisations were conducted with high-shutter speed digital still- and video-cameras.

### 2.2 DATA PROCESSING

The measurement principle of conductivity probes is based upon the difference in electrical resistivity between air and water. The resistance of water is one thousand times lower than the resistance of air bubbles. When the probe tip is in contact with water, current will flow between the tip and the supporting metal; when it is in contact with air no current will flow. A sketch of doubletip conductivity probe is presented in Figure 2-2A. Typical probe signals are shown in Figure 2-2B. Each steep drop of probe output signal corresponds to an air bubble pierced by the probe tip. Although the signal is theoretically rectangular, the probe response is not square because of the finite size of the tip, the wetting/drying time of the interface covering the tip and the response time of the probe and electronics. Herein the signal was processed using a single threshold technique and the threshold was set between 45 and $55 \%$ of the full air-water voltage range. A sensitivity analysis was conducted with thresholds between 40 and $60 \%$ of the voltage range (TOOMBES 2002). The results showed little effect of the threshold on air-water flow properties. (Time-variations of the water voltage during the scan period (i.e. 20 sec.) was sometimes a problem however. Some data
${ }^{1}$ The discharge measurements were based upon GONZALEZ' (2005) detailed velocity distribution measurements on the broad-crested weir. Present discharge estimates are based upon the re-analysis of his results and the resulting calibration curve :

$$
\frac{\mathrm{Q}_{\mathrm{W}}}{\mathrm{~W}}=\left(1.013-0.37 * \frac{\mathrm{H}_{1}-\Delta \mathrm{z}}{\mathrm{~W}}\right) * \sqrt{\mathrm{~g} *\left(\frac{2}{3} *\left(\mathrm{H}_{1}-\Delta \mathrm{z}\right)\right)^{3}}
$$

where $H_{1}$ is the upstream total head, $\Delta \mathrm{z}$ is the weir crest elevation and W is the channel width. The above relationship was derived for $0.05 \leq\left(\mathrm{H}_{1}-\Delta \mathrm{z}\right) / \mathrm{W} \leq 0.22$
sets had to be rejected when the water voltage variations exceeded $10 \%$ of the air-water voltage range during a scan.)

Fig. 2-1 - Photographs of the experimental channel with a rough stepped invert $\left(\theta=22^{\circ}, \mathrm{h}=0.1 \mathrm{~m}\right)$ (A) Details of the step roughness (Configuration A) - Note the 13.5 cm long pen for scale

(B) Nappe flow operation $\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h}=0.4, \mathrm{Re}=1.0 \mathrm{E}+5\right)$ - Sub-regime NA3 without hydraulic jump

The basic probe outputs were the void fraction, bubble count rate, velocity, turbulence intensity and air/water chord size distributions (e.g. CROWE et al. 1998, CHANSON 2002,2004b). The void fraction C is the proportion of time that the probe tip is in the air. The bubble count rate F is the number of bubbles impacting the probe tip. The bubble chord times provide information on the air-
water flow structure. With a dual-tip probe design, the velocity measurement is based upon the successive detection of air-water interfaces by two tips. In turbulent air-water flows, the detection of all bubbles by each tip is highly improbable and it is common to use a cross-correlation technique (e.g. CAIN and WOOD 1981, CROWE et al. 1998). The time-averaged air-water velocity equals: $V=\Delta x / T$, where $\Delta x$ is the distance between tips and $T$ is the time for which the cross-correlation function is maximum (Fig. 2-3).
The turbulence level Tu may be derived from the broadening of the cross-correlation function compared to the auto-correlation function :

$$
\begin{equation*}
\mathrm{Tu}=0.851 * \frac{\sqrt{\Delta \mathrm{~T}^{2}-\Delta \mathrm{t}^{2}}}{\mathrm{~T}} \tag{2-1}
\end{equation*}
$$

where $\Delta \mathrm{T}$ is a time scale satisfying : $\mathrm{R}_{\mathrm{xy}}(\mathrm{T}+\Delta \mathrm{T})=0.5 * \mathrm{R}_{\mathrm{xy}}(\mathrm{T}), \mathrm{R}_{\mathrm{xy}}$ is the normalised crosscorrelation function, and $\Delta \mathrm{t}$ is the characteristic time for which the normalised autocorrelation function $\mathrm{R}_{\mathrm{xx}}$ equals 0.5 (Fig. 2-3) (CHANSON and TOOMBES 2001a,b, 2002a). Physically a thin and narrow cross-correlation function must correspond to little fluctuations in the interfacial velocity, hence a small turbulence level (Fig. 2-3, dotted line). Conversely, a broad crosscorrelation function implies large turbulence level.
Equation (2-1) was derived for two-phase mixtures on pneumatic conveyor (KIPPHAN 1977) and for high-velocity turbulent bubbly flows (CHANSON and TOOMBES 2002a). It is a measure of the average velocity fluctuations and it was validated for dispersed phase, including in open channel flows with the LDA data of OHTSU and YASUDA (1997). It is acknowledged that the development is based upon few key assumptions (App. A). The turbulence level, defined in Equation (2-1), is not a point measurement, but some spatial average between probe sensors. A further approximation is that a characteristic time $\mathrm{t}^{\prime}$ equals the time T for which the crosscorrelation function is maximum (CHANSON and TOOMBES 2002a, pp. 1756-57). CHANSON and TOOMBES explicitly stated : "there is no indication of its validity for $0.05<\mathrm{C}<0.95$ " ! Since the results (Eq. (2-1)) are valid in very disperse phase and yield monophase flow observations, the approximation might be reasonable, at least in disperse phase. For $\mathrm{C}<0.05$ and $\mathrm{C}>0.95$, Equation (2-1) might not be equal to the "true" turbulence intensity, but it remains an expression of some turbulence level or average velocity fluctuations.
The autocorrelation function provides further information on the signal. A characteristic measure is the "noise" defined as :

$$
\begin{equation*}
\text { Noise }=0.851 * \frac{\Delta t}{T} \tag{2-2}
\end{equation*}
$$

where $\Delta t$ is the characteristic time for which the normalised autocorrelation function $R_{x x}$ equals 0.5 (Fig. 2-3). The "noise" is somewhat comparable to an integral time scale of the voltage signal.
Bubble chord sizes may be calculated from the raw probe signal outputs. The results provide a complete characterisation of the streamwise distribution of air and water chords. In turn information on the flow structure may be analysed in terms of particle clustering and grouping (CHANSON and TOOMBES 2002a). In this study, two air bubbles formed parts of a cluster when the water chord separating the bubbles was less than one tenth of the mean water chord size.
Although the autocorrelation function provides some information, a Fourier spectral analysis of the probe signal gives further information on the frequency distribution and the reproductibility of the signal with itself, that is related to the air+water length scale distribution of the flow (CHANSON and GONZALEZ 2004, GONZALEZ 2005). The auto power spectrum provides some information on the sensor signal periodicity. In a typical auto power spectrum, the power spectral density (PSD) curve displays the partitioning of power, or voltage variation (interface length scale fluctuation), according to frequency. The frequency of voltage fluctuation $(f)$ is a function of the velocity at which the interfaces are convected past the probe (local flow velocity V ) and on the air+water length scale that may be calculated as $\lambda=\mathrm{V} / f$.

A combined analysis of chord length, clustering and spectral characteristics describes the air-water flow structure and its behaviour.

(B) Typical probe signal output and corresponding binary signal

Fig. 2-3 - Sketch of the cross-correlation and auto-correlation functions deduced from the analysis of a dual-tip phase-detection probe signal analysis

Quality control, scan frequency and scan duration
Phase-detection probes are very sensitive devices and they are susceptible to a number of problems. In the present study, the quality control procedure developed by TOOMBES (2002, pp. 70-72) was applied thoroughly. Specifically, the probe signals were checked systematically for (1) long-term signal decays often induced by probe tip contamination, (2) short-term signal fluctuations caused by debris and water impurities, (3) electrical noise and (4) non-representative samples. While most quality control procedure can be automatised, it must be stressed that human supervision and intervention are essential to validate each quality control step.
The scan frequency determines the resolution of the intrusive phase-detection probe, in particular the accuracy of chord size measurement, minimum detectable air/water chord length, and the accuracy of the interfacial velocity :

$$
\begin{equation*}
\Delta \mathrm{ch}=\frac{\mathrm{V}}{\mathrm{~F}_{\text {scan }}} \tag{2-2}
\end{equation*}
$$

$$
\begin{equation*}
\frac{\Delta \mathrm{V}}{\mathrm{~V}}=1-\left(1+\frac{\mathrm{V}}{\mathrm{~F}_{\text {scan }}^{*} \Delta \mathrm{x}}\right)^{-1} \tag{2-3}
\end{equation*}
$$

where ch is the chord size, V is the velocity, $\mathrm{F}_{\text {scan }}$ is the scan rate and $\Delta \mathrm{x}$ is the streamwise distance between probe sensors. Herein the scan frequency was 20 kHz per sensor and the streamwise distance between probe sensor was : $\Delta x=7.74 \mathrm{~mm}$.
TOOMBES (2002, pp. 69-70) performed a detailed sensitivity analysis of the scan period using the double-tip conductivity probe in nappe flows. His results showed that the scan period had to be greater than 5 seconds. In the present study, a scan duration of 20 seconds was selected.

### 2.3 DATA ACCURACY

The water discharge was measured with an accuracy of about $2 \%\left(^{2}\right.$ ).
The translation of the double-tip conductivity probe in the direction normal to the channel invert was controlled with an error of less than 0.5 mm . The accuracy on the longitudinal probe position was estimated as $\Delta \mathrm{x}<+/-0.5 \mathrm{~cm}$. The error on the transverse position of the probe was less than 1 mm .
With the double-tip conductivity probe, the error on the air concentration (void fraction) measurements was estimated as : $\Delta \mathrm{C} / \mathrm{C}=4 \%$ for $0.05<\mathrm{C}<0.95, \Delta \mathrm{C} / \mathrm{C} \sim 0.002 /(1-\mathrm{C})$ for $\mathrm{C}>$

[^0]0.95 , and $\Delta \mathrm{C} / \mathrm{C} \sim 0.005 / \mathrm{C}$ for $\mathrm{C}<0.05$. The mean air-water velocities were computed with a crosscorrelation technique. The analysis of the velocity field and chord length distributions implied no slip between the air and water phases. The error on the mean air-water velocity measurements was estimated as : $\Delta \mathrm{V} / \mathrm{V}=5 \%$. for $0.05<\mathrm{C}<0.95, \Delta \mathrm{~V} / \mathrm{V}=10 \%$. for $0.01<\mathrm{C}<0.05$ and $0.95<\mathrm{C}<$ 0.99 (CUMMINGS and CHANSON 1997, CHANSON and BRATTBERG 1997). The guidelines are consistent with Equation (2-3). With the two-tip conductivity probe, the minimum detectable bubble chord length was about $150 \mu \mathrm{~m}$ in a $3 \mathrm{~m} / \mathrm{s}$ flow based upon a data acquisition frequency of 20 kHz per channel (Eq. (2-2)).

### 2.4 CHANNEL CONFIGURATIONS AND GEOMETRIES

In the present study, four step surface configurations were tested systematically (Table 2-1). In Configuration A , the vertical and horizontal step faces were covered by rough screens with square patterns ( 16 mm size, 1 mm thick, 8 mm high) (Fig. 2-4 and 2-5). In Configuration B, only the vertical step faces were covered with the same rough screens. The horizontal step faces were smooth. In Configuration C, the horizontal step faces were covered with the rough screens while the vertical faces were smooth. The last configuration was a smooth stepped cascade. It was similar to the flow configurations used by CHANSON and TOOMBES (2001a,2002a) and GONZALEZ (2005).

The hydraulic roughness of the screens was tested independently in a 20 m long, 0.25 m wide tilting flume with glass sidewalls (App. B). For a 10 m length, the channel bed was covered with the rough screen pattern (Fig. 2-5B). The gradually-varied free-surface profile was recorded in the fullydeveloped flow region for a range of flow rates ( 0.017 to $0.04 \mathrm{~m}^{3} / \mathrm{s}$ ) and bed slopes ( $\mathrm{S}_{\mathrm{O}}=0.09$ to $0.15)$. For each run, the average boundary shear stress $\tau_{\mathrm{o}}$ was calculated from the friction slope $\mathrm{S}_{\mathrm{f}}$ which satisfied the differential form of the energy equation :

Notes : Re : flow Reynolds number defined in terms of hydraulic diameter.

$$
\begin{equation*}
\frac{\partial \mathrm{H}}{\partial \mathrm{x}}=-\mathrm{S}_{\mathrm{f}} \tag{2-4}
\end{equation*}
$$

where H is the total head and x is the streamwise coordinate (HENDERSON 1966, CHANSON 1999,2004a). The average boundary shear stress $\tau_{\mathrm{O}}$ along the wetted perimeter $(\mathrm{W}+2 * \mathrm{~d})$ is the combination of bed shear stress and sidewall shear stress weighted by their respective wetted perimeter. Hence the bed shear stress $\tau_{\text {screen }}$ was deduced as :

$$
\begin{equation*}
\tau_{\mathrm{o}} *(\mathrm{~W}+2 * \mathrm{~d})=\tau_{\text {screen }} * \mathrm{~W}+\tau_{\mathrm{wall}} * 2 * \mathrm{~d} \tag{2-5}
\end{equation*}
$$

where W is the channel width, d is the water depth and $\tau_{\text {wall }}$ is the glass sidewall shear stress which was deduced from the Moody diagram assuming an equivalent roughness height $\mathrm{k}_{\mathrm{S}}=0.1 \mathrm{~mm}$ (IDELCHIK 1969,1986,1994, HENDERSON 1966, CHANSON 2004a).
The results in terms of Darcy friction factors are reported in Figure 2-6A and compared with Colebrook-White formula. The correlation is poor but the Colebrook-White formula is not truly applicable to present roughness elements. Indeed the screens are porous and the induced flow resistance is a combination of skin friction and form drag. In Figure 2-6B, the data are shown in terms of the relative roughness height $\mathrm{k} / \mathrm{D}_{\mathrm{H}}$ where $\mathrm{k}=8 \mathrm{~mm}$ and $\mathrm{D}_{\mathrm{H}}$ is the hydraulic diameter. The results are compared with fully-rough turbulent flow results. Overall, the equivalent Darcy friction factor of the screens ranged from $\mathrm{f}_{\text {Screen }}=0.05$ to 0.08 , corresponding to a Gauckler-Manning coefficient of about 0.016 to $0.02 \mathrm{~s} / \mathrm{m}^{1 / 3}$. The results were basically independent of Reynolds number and the flow conditions were fully-rough turbulent. The data were best correlated by :

$$
\begin{equation*}
\frac{1}{\sqrt{\mathrm{f}_{\text {screen }}}}=0.252 *\left(\frac{\mathrm{k}}{\mathrm{D}_{\mathrm{H}}}\right)^{-0.823} \tag{2-6}
\end{equation*}
$$

with a normalised correlation coefficient of 0.783 , where k is the screen height $(\mathrm{k}=8 \mathrm{~mm})$. Equation (2-4) is shown in Figure 2-6B
The best correlation with the Colebrook-White formula was achieved for an equivalent sand roughness height $\mathrm{k}_{\mathrm{S}}{ }^{\prime}=6.6 \mathrm{~mm}$ that is comparable to the screen thickness $\mathrm{k}=8 \mathrm{~mm}$.

### 2.5 FLOW CONFIGURATIONS

Experiments were conducted for flow rates ranging from 0.004 to $0.220 \mathrm{~m}^{3} / \mathrm{s}$ although the focus was on the highly aerated skimming flows (Table 2-1). Detailed air-water flow measurements were performed for flow rates between 0.11 and $0.2 \mathrm{~m}^{3} / \mathrm{s}$ corresponding to dimensionless discharges $\mathrm{d}_{\mathrm{c}} / \mathrm{h}=1.1$ to 1.5 and flow Reynolds numbers $\rho^{*} \mathrm{U}_{\mathrm{w}}{ }^{*} \mathrm{D}_{\mathrm{H}} / \mu$ between $4.6 \mathrm{E}+5$ and $7.3 \mathrm{E}+5$, where $\mathrm{d}_{\mathrm{c}}$ is the critical flow depth, $h$ is the step height, $\mathrm{U}_{\mathrm{w}}$ is the depth-averaged velocity, $\mathrm{D}_{\mathrm{H}}$ is the hydraulic diameter, and $\rho$ and $\mu$ are the water density and dynamic viscosity respectively.
Present measurements were performed systematically at step edges downstream of the inception
point of free-surface aeration and between adjacent step edges (i.e. above recirculation cavity). Above the cavities, measurements were conducted at step edge and at 3 streamwise locations $X_{0}=$ $0.25,0.5$ and 0.75 , where $\mathrm{X}_{\mathrm{O}}=\mathrm{x}^{\prime} / \mathrm{L}_{\mathrm{cav}}, \mathrm{x}^{\prime}$ is the streamwise distance measured from the upstream step edge and $L_{c a v}$ is the cavity length $\left(L_{c a v}=\sqrt{h^{2}+1^{2}}\right)$. For each configuration, measurements were repeated systematically. A total of more than 90 vertical profiles were recorded with a minimum of 25 measurement points per profile. At each measurement point, the data acquisition yielded 400,000 data per probe sensor. (Altogether the present data set encompassed over 1 billion of samples.) Note that uniform equilibrium flow conditions were not achieved at the downstream end of the chute because the flume was relatively short.

## 3. BASIC FLOW PATTERNS

Waters cascading down stepped chutes with smooth step faces are highly turbulent self-aerated flows. They are difficult to describe, mainly because of the different flow regimes observed. For a given chute geometry, the type of stepped flow regime is a function of the discharge and is usually divided into three separate flow regimes.
For small discharges, water cascades down the chute step by step as a succession of nappes sometimes followed by a hydraulic jump, this flow regime is called Nappe flow.
If the water discharge is increased, a transition flow regime can be observed, this regime is characterised by strong hydrodynamic fluctuations, significant splashing, large amounts of spray near the free-surface and longitudinal variations of the flow properties from one step to another (Fig. 3-1). Transition flows are further divided in sub regimes TRA1 for low water discharges, where small and large air-filled cavities alternate irregularly in the step cavities located downstream of inception point and TRA2 for the upper range of transition flows where different sized air-filled cavities alternate with flow-filled recirculating vortices at every step in locations downstream the inception point (CHANSON and TOOMBES 2004).
For larger discharges, the flow skims over the pseudo-bottom formed by the steps as a coherent stream and intense recirculating vortices are observed between step edges beneath the pseudobottom. For flat to moderate slope stepped chutes ( $5.7^{\circ}<\theta<30^{\circ}$ ) with smooth step faces CHANSON (2001) and OHTSU et al. (2004) proposed further division of the skimming flow in two sub regimes: SK1 sub-regime for the lower range of skimming flow discharges, where the wake and recirculating eddy formed between step edges do not extend the full step length allowing the main water stream to impact in the horizontal face of the step and SK2 sub regime for the upper range of discharges, where the wake and recirculating eddy region extend the full step length sometimes interfering with the developing wake of the subsequent step.

Fig. 3-1 - Nappe/Transition flow at Duralie coal mine stepped spillway NSW, Australia (on 23 March 2005; Courtesy of Tony MARSZALEK, Gilbert \& Associates Pty LTD, Brisbane)

Although the scope of this study is on skimming flows, detailed visualizations were conducted for rough step configurations (Table 2-1) with flow rates ranging from 0.014 to $0.182 \mathrm{~m}^{3} / \mathrm{s}$ to document the influence of the step roughness on the nappe, transition and skimming flow regimes. Results showed that the classification of flow regimes with rough steps and the conditions for changes in
flow regimes were identical on all rough step configurations ( $\mathrm{A}, \mathrm{B}, \mathrm{C}$ ) and on smooth step chutes. The results are summarised in Table 3-1.
CHANSON (2001) and OHTSU et al. (2004) recommended approximate limits for the changes between flow regimes in smooth stepped chutes. Present data are shown in Fig. 3-2 and compared with the correlations of CHANSON (2001) and OHTSU et al. (2004). Present results showed that the different roughness placed on to the steps had no influence on the type of flow regime nor on the flow regime variation.

Table 3-1 - Flow regimes for stepped chutes with smooth and rough step faces (Configurations A, $\mathrm{B}, \mathrm{C} \& \mathrm{~S}, \theta=21.8^{\circ}, \mathrm{h}=0.1 \mathrm{~m}$ )

Fig. 3-2 - Comparison of flow regime transition observations in rough step faced stepped chutes with transition criterions for smooth step faced stepped chutes - NA-TRA : change from nappe to transition flow regime; TRA-SK : change from transition to skimming flow regime

Visual observations suggested a number of different flow patterns for chutes with step roughness. These were seen more specifically in the flow recirculation zones located between the step edges beneath the main stream. Upstream of the point of inception, more aerated cavities were
consistently observed for Configuration A than for the rest of the configurations including smooth steps (Fig. 3-3).
In waters skimming down Configuration A with a discharge of $\mathrm{d}_{\mathrm{c}} / \mathrm{h}=1.25$, the air entrainment started at the cavity in between steps $7 \& 8$ and three aerated cavities were observed upstream this point (Fig. 3-3A). For identical flow conditions in Configurations B and C, the inception point was also located between steps 7 and 8 for both scenarios but only one to two aerated cavities were observed upstream of the inception point (Fig. 3-3B \& C). For the same discharge in smooth stepped chutes, the inception point was further upstream, between step edges $6 \& 7$. In addition, only 1 to 2 aerated cavities were seen upstream the point of inception.

Fig. 3-3 - Recirculation cavities upstream the point of inception

(A) Skimming flow in Configuration $\mathrm{A}\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h}=\right.$ $1.25, \mathrm{~d}_{\text {crest }} / \mathrm{h}=1.3$ ) - Inception point: between step edges 7 \& 8 .

(C) Skimming flow in Configuration $\mathrm{C}\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h}=\right.$ $1.25, \mathrm{~d}_{\text {crest }} / \mathrm{h}=1.3$ ) - Inception point: between step edges $7 \& 8$.

(B) Skimming flow in Configuration $\mathrm{B}\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h}=\right.$ $1.25, \mathrm{~d}_{\text {crest }} / \mathrm{h}=1.3$ ) - Inception point: between step edges $7 \& 8$.

(D) Skimming flow in Configuration S smooth steps $\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h}=1.25, \mathrm{~d}_{\text {crest }} / \mathrm{h}=1.3\right)$ - Inception point: between step edges 6 \& 7

In the aerated flow region downstream of the inception point, recirculation cavity patterns were observed in rough and smooth stepped chutes. Some differences were consistently observed. Recirculating eddies with clear water cores in the step corners were seen in Configurations A \& C while recirculating vortices covering the whole cavity length occurred in chutes for Configuration B and for chutes with smooth steps. This is seen in Figure 3-4, for example, where clear water cores are observed in the step corners underneath the recirculating eddies for Configurations $\mathrm{A} \& \mathrm{C}$ (Fig. $3-4 \mathrm{~A} \& \mathrm{C}$ ) while recirculating eddies covering the whole cavity without clear water cores are observed for Configuration B and smooth stepped chutes (Fig. 3-4B \& D).
In the present study, the location of the inception point differed for chutes with and without step roughness, specifically for the larger relative discharges tested ( $\mathrm{d}_{\mathrm{C}} / \mathrm{h}=1.39$ \& 1.5). Basically, the inception point was further downstream for chutes with rough steps (Refer to Appendix C for
detailed data) ( ${ }^{1}$ ). Positions of inception point are compared with smooth faced stepped chutes in Table 3-1 and Fig. 3-5. The results indicate that the inception point distance from the crest $\mathrm{L}_{\mathrm{I}}$ was approximately $35 \%$ greater for rough step faced spillways than that for smooth step faced chutes. The findings suggest that the turbulent boundary layer growth is 'slower" on rough stepped invert and that lesser rate of energy dissipation occurred in the upstream clear-water flow region on the rough stepped chute.
The finding is counter-intuitive compared to smooth-invert chute flows where increased bed roughness is associated with a shorter clear-water flow region (e.g. WOOD et al. 1983).
For the present study, the data corresponding to the rough-step-faced configurations were best correlated by:

$$
\begin{equation*}
\frac{\mathrm{L}_{\mathrm{I}}}{\mathrm{~h} * \cos \theta}=8.15+11.43 * \operatorname{Ln}(\mathrm{~F} *) \tag{3-5}
\end{equation*}
$$

(Configurations A, B, C)
while data corresponding to the smooth step chute (Config. S) were best fitted by:

Fig. 3-4 - Recirculation cavities for rough and smooth step configurations

(A) Configuration $\mathrm{A}\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h}=1.0, \mathrm{~d}_{\text {crest }} / \mathrm{h}=1.06\right)$ Cavity located between step edges $7 \& 8$, Inception point: between step edges $6 \& 7$.

(C) Skimming flow in Configuration $\mathrm{C}\left(\mathrm{d}_{\mathrm{C}} / \mathrm{h}=\right.$ $1.25, \mathrm{~d}_{\text {crest }} / \mathrm{h}=1.3$ ) - Cavity located between step edges $6 \& 7$, Inception point: between step edges $7 \& 8$.

(B) Configuration $\mathrm{B}\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h}=1.1, \mathrm{~d}_{\text {crest }} / \mathrm{h}=1.1\right)-$ Cavity: between step edges $5 \& 6$, Inception point: step edge 7 .

(D) Skimming flow in Configuration S smooth steps ( $\mathrm{d}_{\mathrm{c}} / \mathrm{h}=1.25, \mathrm{~d}_{\text {crest }} / \mathrm{h}=1.3$ ) - Cavity located between step edges $5 \& 6$, Inception point: between step edges $6 \& 7$.

| 1.5 | 1.7 | Step $7(1.62 \mathrm{~m})$ | Step $9(2.15 \mathrm{~m})$ | Between step edges <br> $8 \& 9(\sim 2.02 \mathrm{~m})$ | Between step edges <br> $8 \& 9(\sim 2.02 \mathrm{~m})$ |

Note: Configuration A: Vertical and horizontal covered with a rough screen with square patterns, Configuration B: Only Vertical faces covered with the screed, Configuration C: Only horizontal faces covered with the screen, Grid's squares size: ( 16 mm area, 1 mm thickness and 8 mm high ), $\mathrm{d}_{\mathrm{c}}$ is the critical depth, $\mathrm{d}_{\text {crest }}$ is the depth measured above the crest of the weir, $h$ is the step height and $L_{I}$ is distance form the point of inception to the step edge 1 (Refer to Appendix C).

Fig. 3-5 - Comparison of inception point locations for spillways with smooth (CG2005 data set) and rough step faces (Config. A, B \& C)

where $\mathrm{L}_{\mathrm{I}}$ is the length to the point of inception, h is the vertical step height, $\theta$ is the channel slope, and $\mathrm{F} *$ is the step roughness Froude number defined as:

$$
\begin{equation*}
\mathrm{F}_{.}=\frac{\mathrm{q}_{\mathrm{w}}}{\sqrt{\mathrm{~g} \cdot \sin \theta \cdot \mathrm{k}_{\mathrm{s}}^{3}}} \tag{3-7}
\end{equation*}
$$

where $\mathrm{k}_{\mathrm{s}}=\mathrm{h}^{*} \cos \theta$ is the roughness height measured perpendicular to the flow direction and $\mathrm{q}_{\mathrm{w}}$ is the water discharge per unit width (CHANSON 1995a).

## 4. AIR-WATER FLOW PROPERTIES

### 4.1 PRESENTATION

This section aims to describe quantitatively the impact of the different step roughness on the airwater flow characteristics. Experimental air-water flow measurements were conducted with a double tip conductivity probe on a near-full-scale stepped chute model with four step roughness configurations (Table 2-1). In the direction normal to the flow, measurements were obtained above and below the pseudo-bottom formed by the step edges up to the spray region. In the flow direction, they were performed at step edges downstream of the point of inception and at three locations in between adjacent step edges $\mathrm{X}_{0}=0.25,0.50$ and 0.75 where $\mathrm{X}_{0}=\mathrm{x}^{\prime} / \mathrm{L}_{\text {cav }}$, $\mathrm{x}^{\prime}$ is the distance from the upstream edge and $\mathrm{L}_{\text {cav }}$ is the cavity length $\mathrm{L}_{\text {cav }}=\sqrt{\mathrm{h}^{2}+1^{2}}$ (Fig. 4-1).
A detailed comparison of flow properties obtained for all tested configurations including smooth steps was conducted. Results included void fraction C, velocity V, turbulence intensity Tu, bubble count rate F and specific interface area a distributions.

Fig. 4-1 Definition sketch of air-water flow properties and location measurements

### 4.2 AIR CONCENTRATION AND VELOCITY DISTRIBUTIONS

Dimensionless air concentration distributions are presented in Fig. 4-2A. The data were obtained for the same flow conditions $\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h} \approx 1.39\right)$ at step edges and at the same dimensionless distance from the inception point $\left(x-L_{\mathrm{I}}\right) / \mathrm{L}_{\text {cav }}=2$. The results are presented in terms of the dimensionless depth $\left(y / d_{c}\right)$ in Fig. 4-2A for the four tested configurations (Table 2-1). Present data are also compared with previous experimental data collected in the same smooth stepped chute $\left(\theta=21.8^{\circ}, \mathrm{h}\right.$ $=0.1 \mathrm{~m}$, Config. S) by CHANSON and TOOMBES (2001a) and GONZALEZ (2005).
Overall the experimental results showed similar distributions of air concentrations at step edges for all configurations (Fig. 4-2A). Results seemed to suggest that air-water flows over rough-step faced chutes were slightly less aerated than in smooth-step chutes. The finding was especially seen in the lower flow region ( $\mathrm{y} / \mathrm{d}_{\mathrm{c}}<0.3$ ), but also in the intermediate air-water region ( $0.3<\mathrm{C}<0.7$ ). This is seen in Figure 4-2A, where a flatter curve $y / d_{c}$ versus $C$ is observed for rough stepped chutes (e.g. Configurations A and C).Void fraction distributions for Configurations A \& C showed a similar trend while distributions for Configuration B were closer to smooth-step data.
Air-water flow velocity distributions corresponding to the same flow conditions as in Figure 4-2A are presented in Figure 4-2B where V is the air-water flow and $\mathrm{V}_{\mathrm{c}}$ is the critical flow velocity. Results showed consistently faster velocities for rough step chutes, especially for Configurations A \& C. Basically, larger flow velocities and slightly less flow aeration were observed systematically
on rough-step chutes at an identical dimensionless distance from the inception point of free-surface aeration. Although the result might be counter-intuitive, the finding was consistently observed for all investigated discharges.

Fig. 4-2 - Dimensionless air water flow distributions for $\mathrm{d}_{\mathrm{c}} / \mathrm{h} \approx 1.37$ and $\left(\mathrm{x}-\mathrm{L}_{\mathrm{I}}\right) / \mathrm{L}_{\mathrm{cav}}=2$

| Configuration | $\mathrm{d}_{\mathrm{c}} / \mathrm{h}$ | x <br> $(\mathrm{m})$ | Step <br> edge | $\mathrm{L}_{\mathrm{I}}$ <br> $(\mathrm{m})$ | $\left(\mathrm{x}-\mathrm{L}_{\mathrm{I}}\right) / \mathrm{L}_{\text {cav }}$ |
| :---: | :---: | :--- | :---: | :---: | :---: |
| A | 1.39 | 2.42 | 10 | 1.88 | 2 |
| B | 1.39 | 2.42 | 10 | 1.88 | 2 |
| C | 1.39 | 2.42 | 10 | 1.88 | 2 |
| CHANSON \& TOOMBES (2001a) | 1.39 | 2.15 | 9 | 1.62 | 2 |
| GONZALEZ (2005) | 1.34 | 1.89 | 8 | 1.35 | 2 |
| Smooth steps) | 2.15 | 9 | 1.62 | 2 |  |

Notes: x is the distance from step edge 1 to the measurement location, $\mathrm{L}_{\mathrm{I}}$ is the length to the point of inception and $\mathrm{L}_{\text {cav }}$ is the cavity length, $\mathrm{L}_{\text {cav }}=0.27 \mathrm{~m}$.
(A) Dimensionless air concentration distributions: C versus $\mathrm{y} / \mathrm{d}_{\mathrm{c}}$

(B) Dimensionless air-water flow velocity distributions: $\mathrm{V} / \mathrm{V}_{\mathrm{c}}$ versus $\mathrm{y} / \mathrm{d}_{\mathrm{c}}$

Comparisons performed throughout the whole experimental data set showed that flow velocities for Configurations A \& C were identical and consistently larger than those for Configuration B. Relatively faster velocities were recorded in Configuration B than on smooth steps, although the difference was small (Fig. 4-2A).
In summary, present results yielded :

$$
\left(\frac{\mathrm{V}}{\mathrm{~V}_{\mathrm{c}}}[\mathrm{~A} \& \mathrm{C}]>\frac{\mathrm{V}}{\mathrm{~V}_{\mathrm{c}}}[\mathrm{~B}]>\frac{\mathrm{V}}{\mathrm{~V}_{\mathrm{c}}}[\text { smooth steps }]\right)
$$

Fig. 4-3 - Air water flow distributions for $\left(\mathrm{d}_{\mathrm{c}} \mathrm{h} \approx 1.37\right)$ and $\left(\mathrm{x}-\mathrm{L}_{\mathrm{I}} / \mathrm{L}_{\mathrm{cav}}=2\right)$, flow conditions and symbols as in Figure 4-2
(A) Dimensionless turbulence intensity distributions: Tu versus $y / \mathrm{d}_{\mathrm{c}}$

(B) Dimensionless bubble count rate distributions: $\mathrm{F}^{\cdot} \mathrm{d}_{\mathrm{c}} / \mathrm{V}_{\mathrm{c}}$ versus $\mathrm{y} / \mathrm{d}_{\mathrm{c}}$

(C) Dimensionless specific interface area distributions: $a \cdot d_{c}$ versus $y / d_{c}$

### 4.3 DISTRIBUTIONS OF TURBULENCE INTENSITY, BUBBLE COUNT RATE AND SPECIFIC INTERFACE AREA

A comparison of experimental dimensionless turbulence intensity, bubble count rate and specific interface area distributions obtained for the same flow conditions ( $\mathrm{d}_{\mathrm{C}} / \mathrm{h} \approx 1.39$ ) at step edges equally separated from the inception point is presented in Fig. 4-3. Turbulence intensity distributions for Configurations A \& C were observed to be consistently lower than those for Configuration B and chutes with smooth steps (Fig. 4-3A). In terms of bubble count rate, Fig.4-3B showed a similar trend, with lowest bubble count rate distributions corresponding to Configurations A \& C. Figure 43C also showed that specific interface area distributions are largest for configurations $\mathrm{B} \& \mathrm{~S}$ (smooth steps).

### 4.4 FLOW PROPERTIES BETWEEN STEP EDGES

Experimental data obtained between step edges are presented in Figures 4-4 and 4-5. The data were obtained at the same dimensionless distances from the inception point $\left(x-L_{I}\right) / \mathrm{L}_{\text {cav }}=1.5$. Air concentration distributions exhibited a similar trend than at step edges with Configurations A \& C showing less aeration than with Configurations B and smooth steps (Fig. 4.4A). Velocity distributions also confirmed that the flows in configurations with rough steps were faster than flows on smooth step chutes (Fig. 4-4B).
Turbulent intensity distributions showed that, between step edges, the flow is more turbulent for Configuration B and smooth step configurations than for Configuration A \& C (Fig.4-5A). The same trend was observed at step edges. Higher values of bubble count rate and specific interface area were recorded for Configurations B and smooth step chutes throughout the flow cross-section than with Configurations A \& C (Fig. 4-5B \& C).
Measurements at step edges and between step edges showed little difference. This consistent trend strongly suggested that roughness configurations placed on the steps affected the flow characteristics both below and above the pseudo-bottom formed by the step edges.

Fig. 4-4 - Air water flow distributions between step edges $\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h} \approx 1.37\right.$, $\left.\left(\mathrm{x}-\mathrm{L}_{\mathrm{l}}\right) / \mathrm{L}_{\text {cav }}=1.5\right)$

| Configuration | $\mathrm{d}_{\mathrm{c}} / \mathrm{h}$ | $\mathrm{x}(\mathrm{m})$ | $\mathrm{X}_{0}$ | Location | $\mathrm{L}_{\mathrm{I}}$ <br> $(\mathrm{m})$ | $\left(\mathrm{x}-\mathrm{L}_{\mathrm{I}}\right)$ <br> $/ \mathrm{L}_{\text {cav }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| A | 1.39 | 2.285 | 0.5 | Between step <br> edges 9 \& 10 | 1.88 | 1.5 |
| B | 1.39 | 2.42 | 0.5 | Between step <br> edges 9 \& 10 | 1.88 | 1.5 |
| C | 1.39 | 2.42 | 0.5 | Between step <br> edges 9 \& 10 | 1.88 | 1.5 |
| CHANSON and | 1.5 | 1.75 | 0.5 | Between step <br> edges 7 \& 8 | 1.35 | $\sim 1.5$ |
| TOOMBES (2001) | 1.34 | 2.15 | 0.5 | Between step <br> edges 8 \& 9 | 1.62 | $\sim 1.5$ |

Note: x is the distance from step edge 1 to the measurement location, $\mathrm{L}_{\mathrm{I}}$ is the length to the point of inception, $\mathrm{X}_{0}=\mathrm{x}^{\prime} / \mathrm{L}_{\text {cav }}, \mathrm{x}^{\prime}$ is the distance downstream the nearest step edge and $\mathrm{L}_{\text {cav }}$ is the cavity length $\mathrm{L}_{\mathrm{cav}}=0.27 \mathrm{~m}$.
(A) Dimensionless air concentration distributions: $C$ versus $y / d_{c}$

(B) Dimensionless air-water flow velocity distributions: $\mathrm{V} / \mathrm{V}_{\mathrm{c}}$ versus $\mathrm{y} / \mathrm{d}_{\mathrm{c}}$

Fig. 4-5 - Air-water flow properties between step edges $\mathrm{d}_{\mathrm{c}} \mathrm{h} \approx 1.37$, $\left(\mathrm{x}-\mathrm{L}_{\mathrm{l}}\right) / \mathrm{L}_{\mathrm{cav}}=1.5$, flow conditions and symbols as Figure 4-4
(A) Dimensionless turbulence intensity distributions: Tu versus $\mathrm{y} / \mathrm{d}_{\mathrm{c}}$

(B) Dimensionless bubble count rate distributions: $\mathrm{F} \cdot \mathrm{d}_{\mathrm{c}} / \mathrm{V}_{\mathrm{c}}$ versus $\mathrm{y} / \mathrm{d}_{\mathrm{c}}$

(C) Dimensionless specific interface area distributions: ad $\mathrm{d}_{\mathrm{c}}$ versus $\mathrm{y} / \mathrm{d}_{\mathrm{c}}$

## 5. AIR-WATER CHORD PROPERTIES

Air-water flow experimental measurements were also analysed in terms of the streamwise air and water structures detected by the probe tip to obtain a microscopic description of the flow.
In bubbly flows, an air bubble is commonly thought to be a discrete pocket of air completely surrounded by water. For regions of low air concentration ( $\mathrm{C}<0.3$ ) such air-bubbles do exist. Conversely, in spray regions defined as $\mathrm{C}>0.7$, water droplets completely surrounded by air are likely to be found. However, in the intermediate zone ( $0.3<\mathrm{C}<0.7$ ), the air-water mixture is complex and difficult to describe. It is also difficult to identify the exact nature of the air-water flow because of the diversity in shape and size of the observed air-bubbles and water droplets, as spherical and irregular air-bubbles in water, semi-elliptical water droplets in air, fluctuations near the free surface or a combination of the above can be observed in a skimming flow. TOOMBES (2002) observed that the small probability of the probe tip piercing an air bubble or water droplet on its centreline further complicates the air-water flow structure identifying process.
Using a conductivity probe aligned in the flow direction, only streamwise air-water structures bounded by air-water interfaces are detected by the tip. The probe signal provides information on the chord size of air-bubbles and water droplets comprising the flow (Fig. 5-1).

Fig. 5-1 - Air-water interface detection with a conductivity probe

Air bubble/water droplet chord sizes ( $\mathrm{ch}_{\mathrm{a}}$ and $\mathrm{ch}_{\mathrm{w}}$ ) are calculated assuming the velocity of the detected bubbles $\mathrm{V}_{\mathrm{b}}$ to be identical to the local interfacial velocity (no-slip condition) as:

$$
\begin{align*}
& \mathrm{ch}_{\mathrm{a}}=\mathrm{V}_{\mathrm{b}} \cdot \Delta \mathrm{t}_{\mathrm{a}}  \tag{5-1A}\\
& \mathrm{ch}_{\mathrm{w}}=\mathrm{V}_{\mathrm{b}} \cdot \Delta \mathrm{t}_{\mathrm{w}} \tag{5-1B}
\end{align*}
$$

where $\Delta t_{\mathrm{a}}$ is the time between a water-to-air interface and the following air-to-water interface and $\Delta \mathrm{t}_{\mathrm{w}}$ is the time between an air-to-water interface and the following water-to-air interface (Fig. 5-1). Skimming flows comprise a broad range of chord sizes and is common practice to present its distribution as a histogram where the horizontal axis represents discrete intervals of size $\Delta$ ch and the vertical axis the percentage of the indicated chord sizes detected by the probe during the sample time (e.g. CHANSON and TOOMBES 2002a, YASUDA and CHANSON 2003, GONZALEZ 2005, TOOMBES 2002).
Average chord sizes were calculated from the continuity equation for air or water as:

$$
\begin{align*}
& \overline{\mathrm{ch}_{\mathrm{a}}}=\frac{\overline{\mathrm{V}_{\mathrm{b}}} * \mathrm{C}}{\mathrm{~F}}  \tag{5-2A}\\
& \overline{\mathrm{ch}_{\mathrm{w}}}=\frac{\overline{\mathrm{V}}_{\mathrm{b}} *(1-\mathrm{C})}{\mathrm{F}}
\end{align*}
$$

Water droplets (5-2B)
where $\overline{\mathrm{V}_{\mathrm{b}}}$ is the mean interfacial velocity, C is the air concentration and F is the bubble count rate.
A comparison of experimental chord size distributions obtained in the bubbly flow ( $\mathrm{y}>0, \mathrm{C}<0.3$ ), spray ( $\mathrm{C}>0.7$ ) and cavity recirculation ( $\mathrm{y}<0, \mathrm{C}<0.3$ ) regions is presented in Figures 5-2 to 5-4 for Configurations A, B, C and S (smooth steps). Analysed data were obtained for the same flow conditions at identical dimensionless distances from the inception point $L_{I}$ for the four tested configurations. Present data were also compared with previous experimental data collected in the smooth faced stepped chute ( $\theta=21.8^{\circ}, \mathrm{h}=0.1 \mathrm{~m}$ ) by GONZALEZ (2005).
Figure 5-2A presents air-bubble chord size distributions obtained in bubbly flow regions ( $\mathrm{C}<0.3$ ) for $\mathrm{d}_{\mathrm{c}} / \mathrm{h} \approx 1.37$ at $\left(\mathrm{x}-\mathrm{L}_{\mathrm{I}}\right) / \mathrm{L}_{\text {cav }}=2$ in Configurations $\mathrm{A}, \mathrm{B}, \mathrm{C}$ and smooth faced step chutes. Figure 5$2 B$ shows water-droplet chord size distributions in spray regions ( $C>0.7$ ) for the same conditions above described. For all distributions, the horizontal axis represents intervals of size $\Delta \mathrm{L}=0.5 \mathrm{~mm}$ (i.e. $0.5=0.5 \mathrm{~mm}<\mathrm{ch}_{\mathrm{a}, \mathrm{w}}<1 \mathrm{~mm}$ ).

Overall, air chord length distributions in bubbly flows ( $\mathrm{y}>0, \mathrm{C}<0.3$ ) followed closely a lognormal probability distribution function in all configurations. This is illustrated in Figure 5-3 where the data are compared with the corresponding log-normal distribution.
Results in terms of number of bubbles detected and chord size distributions demonstrated that the structure of the bubbly and spray flow recorded at step edges was relatively similar for all the configurations. The results suggested that the different roughness placed on the steps did not affect significantly the microscopic-scale structure of the upper flow region.

Fig. 5-2 - Chord size distributions at step edge for $\mathrm{d}_{\mathrm{c}} / \mathrm{h} \approx 1.37$ and $\left(\mathrm{x}-\mathrm{L}_{\mathrm{I}}\right) / \mathrm{L}_{\mathrm{cav}}=2$

| Configuration | $\mathrm{d}_{\mathrm{c}} / \mathrm{h}$ | $\mathrm{x}(\mathrm{m})$ | Step <br> edge | $\mathrm{L}_{\mathrm{I}}$ <br> $(\mathrm{m})$ | $\mathrm{x}-\mathrm{L}_{\mathrm{l}} / \mathrm{L}_{\text {cav }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| A | 1.39 | 2.42 | 10 | 1.88 | 2 |
| B | 1.39 | 2.42 | 10 | 1.88 | 2 |
| C | 1.39 | 2.42 | 10 | 1.88 | 2 |
| S (smooth steps) | 1.39 | 2.15 | 9 | 1.62 | 2 |
| GONZALEZ (2005) | 1.34 | 2.15 | 9 | 1.62 | 2 |

Note: $x$ is the distance from step edge 1 to the measurement location, $L_{I}$ is the length to the point of inception and $\mathrm{L}_{\text {cav }}$ is the cavity length, $\mathrm{L}_{\text {cav }}=0.27 \mathrm{~m}$.
(A) Bubbly flow region ( $\mathrm{y}>0, \mathrm{C}<0.3$ )

Figure 5-4A presents air-bubble and water-droplet chord size distributions recorded in the cavity recirculation between step edges ( $\mathrm{y}<0, \mathrm{C}<0.3$ ). Figure $5-4$ includes also bubbly flow ( $\mathrm{y}>0, \mathrm{C}<$ $0.3)$ and spray $(\mathrm{C}>0.7)$ data recorded at an identical distance from the inception point $\left(x-\mathrm{L}_{\mathrm{I}}\right) / \mathrm{L}_{\mathrm{cav}}=$ 1.25 for all tested configurations.

Results were similar to those obtained at step edges. They also suggested that the microscopic-scale structure in the recirculation cavity flow was barely affected by the step roughness.
(B) Spray region ( $\mathrm{C}>0.7$ )

Fig. 5-3 - Probability distribution functions in bubbly flow region at step edges ( $\mathrm{C}<0.3$ )

Fig. 5-4 - Chord size distributions between step edges $\left(\mathrm{d}_{\mathrm{c}} / \mathrm{h} \approx 1.2,\left(\mathrm{x}-\mathrm{L}_{\mathrm{I}}\right) / \mathrm{L}_{\mathrm{cav}}=1.25\right)$

| Configuration | $\mathrm{d}_{\mathrm{c}} / \mathrm{h}$ | $\mathrm{x}(\mathrm{m})$ | $\mathrm{X}_{0}$ | Location | $\mathrm{L}_{\mathrm{I}}(\mathrm{m})$ | $\mathrm{x}-\mathrm{L}_{\mathrm{I}} / \mathrm{L}_{\text {cav }}$ |

## 6. DISCUSSION

### 6.1 LONGITUDINAL FLOW PROPERTIES

Present results in terms of flow property distributions demonstrated that the presence of different step roughness configurations influenced the air-water flow properties on a stepped chute. Configurations A (roughness in vertical and horizontal faces) and Configuration C (roughness in horizontal face only) exhibited the largest differences, compared to smooth step results. Configuration B results seemed to be barely affected by the step roughness and yielded flow properties very close to those of a smooth stepped chute. Overall, there were only slight differences in terms of void fraction distributions, but the flow velocities were larger for chutes with rough steps while turbulence intensity, bubble count rate and specific interface area were higher in smooth step chute flows.
In terms of depth averaged flow properties, however, results showed little difference between all tested configurations. This is seen in Figure 6-1 where a comparison of depth averaged flow properties is presented. Data include dimensionless maximum bubble count rate $\mathrm{F}_{\text {max }} \cdot \mathrm{d}_{\mathrm{c}} / \mathrm{V}_{\mathrm{c}}$, depth averaged air content $C_{m e a n}$, dimensionless depth $\mathrm{Y}_{90} / \mathrm{d}_{\mathrm{c}}$ for $\mathrm{C}=0.90$ and dimensionless air-water flow velocity $\mathrm{V}_{90} / \mathrm{V}_{\mathrm{c}}$ at $\mathrm{y}=\mathrm{Y}_{90}$. (See Appendix E for detailed experimental data.)

Fig. 6-1 - Depth averaged flow conditions for $\mathrm{d}_{\mathrm{c}} / \mathrm{h} \approx 1.37$
(A) Mean air concentration $\mathrm{C}_{\text {mean }}$

(B) Dimensionless maximum bubble count rate $\mathrm{F}_{\max }{ }^{*} \mathrm{~d}_{\mathrm{c}} / \mathrm{V}_{\mathrm{c}}$

(C) Dimensionless depth at $\mathrm{C}=0.90: \mathrm{Y}_{90} / \mathrm{d}_{\mathrm{c}}$

Such results need to be understood. It is well known that, in skimming flows over smooth faced stepped chutes, a shear layer develops at each step edge and three-dimensional cavity vortices are observed underneath the mainstream. Flow recirculation is maintained through momentum and shear stress exchange between the main stream and cavity flows (Fig. 1-3 and 6-2). For the tested configurations it is hypothesized that the grid acting as step roughness affected the shear layer development at each step edge and the flow recirculation zone between step edges especially in Configurations A \& C, with grids on the horizontal step face. The recirculation eddies with clear water core observed for Configurations A \& C and those covering the whole cavity without clear water core underneath, observed for Configurations B \& S, seem to support this idea (Figs. 3-4 and 6-2).
In Configurations A and C, the roughness grid was placed in the steps horizontal face, generating some uncertainty about where the pseudo-bottom of the chute should start. Indeed both top and bottom of the grid could be the "reference" invert. In the present study, the pseudo-bottom start was set at the top of the grid for configurations A \& C and at the step edge for configurations B \& S due to measurement convenience. One could argue that different pseudo-bottom definitions for each configuration might yield an erroneous comparison of values in terms of relative flow depth $y / d_{c}$,
void fraction C and characteristic depth $\mathrm{Y}_{90}$. However the magnitude of the differences observed in the velocity, turbulence intensity, specific interface area and bubble count rate distribution comparisons seemed to suggest that the air-water flow structure differences observed for each configuration were truly caused by the different roughness configurations ruling out any possibility of measurement inconsistency.
In addition, it is hypothesized that a shear layer develops on the top of the grid placed in the horizontal step face but the grid was porous and water infiltrated through the bottom of the grid allowing some fluid to drain into the step cavity (Fig. 6-2). Such seepage flow was observed visually during experiments. WOOD (1964) and NAUDASCHER and ROCKWELL (1994) stated that fluid injection behind a bluff body is associated with drag reduction. In the same manner, this porous bottom effect, may affect the cavity recirculation patterns and in turn the turbulent dissipation process. This could enhance the flow velocities in the recirculation cavity and within the main stream, as observed in Configurations A \& C (roughness in the horizontal step face).

### 6.2 TURBULENCE STRUCTURE

In skimming flow, turbulence levels are markedly higher than monophase flow results on a smooth invert (e.g. OHTSU and YASUDA 1997, AMADOR et al. 2004a). In skimming flows, OHTSU and YASUDA (1997) and AMADOR et al. (2004a,b) measured turbulence levels upstream of the inception point of air entrainment. With a 1-component LDA system, OHTSU and YASUDA (1997) observed turbulence levels of about $15-25 \%$, while AMADOR et al. (2004a,b) obtained turbulence intensities between 20 to $100 \%$ using a PIV system. Downstream of the inception point of air entrainment, experimental results showed further enhanced turbulence levels for $0.1<\mathrm{C}<0.9$ (e.g. CHANSON and TOOMBES 2002a, Present study).

For all configurations during the present study, the data showed relatively strong correlations between turbulence levels and bubble count rates, associated with a monotonic increase in turbulence intensity with increasing bubble frequencies. This is illustrated in Figure 6-3 showing the relationships between turbulence intensity Tu and dimensionless bubble count rate $\mathrm{F}^{*} \mathrm{~d}_{\mathrm{c}} / \mathrm{V}_{\mathrm{c}}$ at several cross-sections. Present results were consistent with the earlier limited data sets of CHANSON and TOOMBES (2002a,2003) and YASUDA and CHANSON (2003).
At step edges, the results suggested that:

$$
\begin{equation*}
\mathrm{Tu}=0.25+\alpha *\left(\frac{\mathrm{~F} * \mathrm{~d}_{\mathrm{c}}}{\mathrm{~V}_{\mathrm{c}}}\right)^{\beta} \tag{6-1}
\end{equation*}
$$

where Tu is the turbulence level (Section 2, App. A), F is the bubble count rate, $\mathrm{d}_{\mathrm{c}}$ and $\mathrm{V}_{\mathrm{c}}$ are the critical flow depth and velocity respectively. For the present study, the exponent $\beta$ ranged from about 1.0 to 1.9 depending upon the discharge, step edge position and step configuration, and the coefficient $\alpha$ decreased with increasing distance from the inception point of free-surface aeration. The latter trend reflected a longitudinal monotonic increase in bubble count rate (Fig. 6-1B), while the levels of turbulence were roughly independent of the longitudinal location.
In skimming flow above a stepped invert, high turbulence levels are generated by the step cavities (Fig. 2-4C, 3-3 \& 3-4). The resulting turbulent fluctuations acting next to the free surface contribute to a drastic air entrapment and advective dispersion. At the "pseudo-free-surface", air is continuously entrained and released. Interfacial aeration involves both entrainment of air bubbles and formation of water droplets (Fig. 6-4). The exact location of the "pseudo-free-surface" becomes undetermined, and very large bubble count rates and specific interface area were recorded (Fig. 4-3 \& 4-5). The writers hypothesise that large bubble count rates, associated with large number of airwater interfaces, contribute to higher turbulence levels, compared to clear-water skimming flows. This would be consistent with the strong correlation between turbulence levels and bubble count rates shown in Figure 6-3. For $0.05 \leq \mathrm{C} \leq 0.95$, the air-water flow structure is dominated by collisions between particles (bubbles, droplets, packets) and by interactions between particles and turbulence Such dynamic processes are associated continuous bubble/droplet break-up, coalescence and interfacial deformations which contribute to large fluctuations in air-water interfacial velocity. Continuous deformations and modification of air-water interfaces must induce large turbulence levels as measured by an intrusive phase-detection probe.

### 6.3 AIR-WATER EXCHANGES AND SPRAY GENERATION

The study of spray and splashing remains limited in high-velocity water flows (Fig. 6-4). Some researchers used visual techniques ( ${ }^{2}$ ), while others used intrusive phase detection probes (CHANSON 1999, TOOMBES 2002, HONG et al. 2004, CHANSON and GONZALEZ 2004).
AUGIER (1996) measured droplet size distributions beneath full-scale irrigation water guns. He observed that the droplet sizes increased with increasing distance from the jet nozzle, with maximum drop sizes downstream of jet breakup. REIN (1998) discussed drop generation in highvelocity open channel flows. CHANSON (1999) presented relevant experimental evidence for smooth invert chutes, but showed the limitations of REIN's developments. CHANSON and GONZALEZ (2004) used turbulence manipulation to enhance the rate of energy dissipation on a stepped chute, and their results demonstrated a drastic increase in spray production (e.g. Fig. 6-4C). Despite the limited data sets, experimental results in supercritical flows (CHANSON 1999, TOOMBES 2002, CHANSON and GONZALEZ 2004, Present study) and water jets (HONG et al. 2004) showed a wide range of droplet chord lengths at each sampling location (e.g. Fig. 5-2B \& 54 C ). The chord length distributions were skewed with a preponderance of small chord sizes relative to the mean. The probability of droplet chord lengths was the largest for droplet sizes between 0.5 and 5 mm , with decreasing numbers of droplets and decreasing droplet sizes with increasing heights y and decreasing liquid fractions (1-C).

Fig. 6-4 - Photographs of air-water exchanges in spray region looking downstream from weir crest (A) Configuration $\mathrm{A}, \mathrm{d}_{\mathrm{c}} / \mathrm{h}=1.25, \mathrm{Re}=5.5 \mathrm{E}+5$, high shutter speed ( $1 / 250 \mathrm{~s}$ ) - Sequence of 4 shots with 0.5 s between photograph

[^2](B) Configuration $\mathrm{C}, \mathrm{d}_{\mathrm{c}} / \mathrm{h}=1.1, \mathrm{Re}=4.3 \mathrm{E}+5$, inception point at step edge 6 , probe located at step edge 8 , high shutter speed $(1 / 1,000 \mathrm{~s})$

(C) Spray and droplet generation captured with high-shutter speed, looking downstream (CHANSON and GONZALEZ 2004, Configuration B, $\mathrm{d}_{\mathrm{c}} / \mathrm{h}=1.1$, $\mathrm{Re}=4.4 \mathrm{E}+5$ ) (Inset : general view, with the water projection in front the trolley system on the right)

Observations in highly turbulent open channel flows suggested that the spray region (defined as $\mathrm{C}>$ 0.7 ) may be sub-divided into three sub-zones. That is, (1) a spray/splashing region consisting of water droplets and entities surrounded by air ( $0.7<\mathrm{C}<0.9$ ); (2) a spray/mist region ( $0.9<\mathrm{C}<$ 0.99 ) with smaller densities of water droplets, and (3) an outer "foggy/aerosol" region with veryfine water droplets. For void fractions between $70 \%$ and $99 \%$, measured droplet size distributions showed a broad range of droplet sizes from less than 0.05 mm up to more than 40 mm , with a mode around $2-5 \mathrm{~mm}$. Above this spray layer, an upper spray field consisted primarily of very fine droplets (i.e. mist) with a few large (several millimetres) droplets reaching heights in excess of 10 water depths.

## Basic considerations

In the spray region, drop formation results from surface distortion, tip-streaming of ligaments and interactions between eddies and free-surface (e.g. HOYT and TAYLOR 1977, REIN 1998, Fig. 64 C ). The formation and ejection of a droplet must be associated with a transfer of turbulent kinetic energy from the main flow. Once a droplet is ejected, its ejection process is the dominant effect because the droplet response time is nearly two orders of magnitude larger than the air flow response time. The energy of each droplet is a combination its potential energy and kinetic energy, although NIELSEN (2004, Pers. Comm.) suggested possibly some pressure increase induced by surface tension.
In an open channel flow (Fig. 3A), the energy flux per unit area in the spray at a point $\mathrm{M}(\mathrm{x}, \mathrm{y})$ equals :

$$
\begin{equation*}
\rho_{\mathrm{W}} *(1-\mathrm{C}) * \mathrm{~V} * \mathrm{~g} *\left(\mathrm{z}+\frac{\mathrm{V}^{2}}{2 * \mathrm{~g}}+\frac{4 * \sigma}{\rho_{\mathrm{W}} * \mathrm{~g} * \mathrm{~d}_{\mathrm{wd}}}\right) \tag{6-2}
\end{equation*}
$$

where $\rho_{\mathrm{W}}$ is the water density, C is the void fraction and (1-C) is the liquid fraction, V is the velocity, z is the vertical elevation measured above a reference level, $\sigma$ is the surface tension and $\mathrm{d}_{\mathrm{wd}}$ is a characteristic droplet diameter. In Equation (6-2), the three terms in the brackets are proportional respectively the potential energy, the kinetic energy and some pressure work induced by capillary forces. Note that the liquid fraction (1-C) accounts for the droplet density in Equation (6-2).
For millimetric droplets (e.g. $\mathrm{d}_{\mathrm{wd}}=2 \mathrm{~mm}, \mathrm{~V}=3 \mathrm{~m} / \mathrm{s}, \mathrm{z}=50 \mathrm{~mm}$ ), the contribution of each term would correspond to a total head ${ }^{3}$ ) of 50,460 and 14 mm of water respectively for the three terms in brackets. The last term would become significant for sub-millimetric droplets only.

[^3]
## 7. SUMMARY AND CONCLUSION

On a stepped chute, the waters skim over the pseudo-bottom formed by the step edges at large discharges (Fig. 7-1). The skimming flow pattern is associated with very strong recirculation and large vortical structures in the step cavities. To date, the effects of step roughness on the flow properties are little known despite the practical relevance which includes the design of gabion stepped chutes and unprotected roller compacted concrete chutes, and the hydraulics of damaged concrete steps on older structures (Fig. 7-2).
In the present study, the effect of step roughness was investigated systematically in a new series of experiments. The work was performed in a large size facility with step height of 0.10 m , step length of 0.25 m and chute width of 1 m . The results may be extrapolated to larger prototypes based upon an undistorted Froude similitude, although great care must be considered (see discussion in Section 1). Four configurations were thoroughly tested with identical flow conditions : a smooth stepped chute and three configurations with rough step faces (Configurations A, B and C). The latters were achieved by placing rough screens ( 8 mm high) on the step faces : on the vertical faces (Config. B), on the horizontal step faces (Config. C) and on both faces (Config. A). Preliminary tests showed that the equivalent sand roughness height of the screens used as step roughness was about $\mathrm{k}_{\mathrm{s}}{ }^{\prime}=6.6$ mm (App. B). Detailed air-water flow measurements were performed with a dual-tip phase detection probe (sensor size: 0.025 mm ). A total of more than 90 vertical profiles were recorded corresponding to about 2,300 measurement points. At each sampling point, the data acquisition yielded 400,000 data per probe sensor. Basic results included the vertical distributions of air concentration, bubble count rate, air-water velocity, turbulence level, and the air and water chord size distributions at each sampling point.

## Key outcomes

1. The results showed some similarities between all four stepped configurations. Three basic flow regimes were observed : i.e., nappe flow at low discharges, transition flow for intermediate flow rates and skimming flow for large discharges. The flow conditions at the change from one flow regime to another were identical for all four geometries (Section 3).
2. In skimming flows, visual observations showed that the step roughness affected the recirculation patterns in the step cavities. The recirculation regions (i.e. y $<0$ ) were typically more aerated on smooth stepped chute than on rough steps. For the roughest configuration A, clear-water recirculation regions were observed downstream of the inception point of air entrainment. Seepage was also observed through the rough screens. This is believed to have a significant impact on the recirculation flows and on the developing shear layers downstream of each step edge.
3. At a macroscopic level, the effects of step roughness were two-fold. The location of the inception point of free-surface aeration was further downstream than for a smooth stepped chute for an identical flow rate (Section 3). In turn the residual energy at the downstream end of the chute was greater on the rough stepped chute. Although this finding contradicts an "intuitive" perception, it derives from the downstream position of the inception point of air entrainment and the lesser rate of energy dissipation in the upstream clear-water flow region on the rough stepped chute.
4. At a microscopic level, the experimental results showed consistently several trends (Table 7-1). The void fraction distribution results at step edges were very close for all stepped configurations, although there seemed to be slightly less entrained air in the rough stepped chute flows. Bubble count rate distributions indicated systematically lesser bubble count rates in the rough stepped chute flows. At step edges, the velocities of rough stepped chute flows were larger and faster than those of smooth chute flows for a given flow rate and dimensionless location from the inception point of free-surface aeration. This was associated with lower turbulence intensities in rough stepped
channel flows, particularly for $0.2 \leq \mathrm{y} / \mathrm{Y}_{90} \leq 0.8$. Similar trends were also observed above step cavities in between step edges.
A detailed analysis of air and water chord size distributions showed that, at each sampling location, the distributions of air and water chords were broad and spanned over two to three orders of magnitude. That is, from less than 0.2 mm to more than 20 mm typically. In the bubbly flow region ( $\mathrm{C}<0.3$ ), the probability distribution functions of air chord sizes followed closely a log-normal law for all investigated configurations and flow conditions. The results in terms of probability distribution function data were close for all four configurations, although the PDFs of air chord size appeared more peaky for the smooth stepped chute configuration in the bubbly flow region.

(B) Damage concrete step on Gold Creek dam stepped chute in April 1996 - Completed in 1890, the un-reinforced steps were the world's first use of concrete for a stepped spillway ( $\mathrm{h}=1.5 \mathrm{~m}, \mathrm{l}=4 \mathrm{~m}$ )

## General remarks

The present results may provide some information for the design of rough concrete stepped chutes (e.g. Fig. 7-2 \& 7-3). For gabion stepped chutes, however, the flow pattern is affected by both the step face roughness and seepage through the gabions. The latter effect was not studied herein although it may affect significantly the flow field on gabion stepped weirs.
It is acknowledged that the present study was limited to one chute slope $\left(22^{\circ}\right)$ and one type of roughness ( 8 mm high rough screens). Further investigations must be performed with different chute slopes and step roughness to ascertain the findings to other spillway geometries.
Overall the flow properties in the Configuration B (rough vertical faces) were close to the smooth stepped chute flow properties, while relatively close results were obtained with the Configurations A and C .

Fig. 7-3 - Stepped spillway of Les Olivettes dam (France) in March 2003 (Courtesy of Mr and Mrs CHANSON) - Flood mitigation, completed in 1987, RCC dam ( $\mathrm{H}=36 \mathrm{~m}, \mathrm{~L}=254 \mathrm{~m}$ ), catchment area : $29.5 \mathrm{~km}^{2}$, design flow $=290 \mathrm{~m}^{3} / \mathrm{s}, \mathrm{W}=40 \mathrm{~m}$

## ACKNOWLEDGMENTS

The writers acknowledge the review comments by Dr Stefano PAGLIARA (University of Pisa, Italy), Robert JANSSEN (Bechtel Australia), Dr Antonio AMADOR (EST Barreiro, Portugal), Dr Jorge MATOS (IST Lisbon, Portugal) and Dr Jim KELLS (University of Saskatchewan, Canada). They thank them for their generous advice.

The writers acknowledge the technical assistance of Graham ILLIDGE and Clive BOOTH.
They thank Dr Youichi YASUDA and Professor Iwao OHTSU (Nihon University, Japan) for their support and encouragements. Hubert CHANSON thanks all the people who provided further relevant information and photographs.

## APPENDIX A - TURBULENT VELOCITY MEASUREMENTS WITH DUAL-TIP PROBES IN AIR-WATER FLOWS

In turbulent air-water flows, the velocity measurement with a dual-tip intrusive phase-detection probe is based upon the successive detection of air-water interfaces by two tips. The technique assumes that the probe sensors are aligned along a streamline, the bubble/droplet characteristics are little affected by the leading tip, and the bubble impact on the trailing tip is similar to that on the leading tip. In disperse bubbly flows with low void fractions (e.g. C $<2$ to $5 \%$ ), the interfacial velocity of individual particles may be deduced from successive interface detections by both probe sensors. In highly turbulent air-water flows with large void fractions, the successive detections of a bubble by each probe sensor is highly improbable, and it is common to use a cross-correlation technique (e.g. CROWE et al. 1998, CHANSON and TOOMBES 2001a, CHANSON 2002). The time-averaged air-water velocity equals:

$$
\begin{equation*}
\mathrm{V}=\frac{\Delta \mathrm{x}}{\mathrm{~T}} \tag{A-1}
\end{equation*}
$$

where $\Delta \mathrm{x}$ is the distance between probe sensors and T is the average interface travel time for which the cross-correlation function is maximum : i.e., $R_{x y}(T)=R_{\max }$ where $R_{x y}$ is the normalised cross-correlation function and $\mathrm{R}_{\max }$ is the maximum cross-correlation value (Fig. A-1).

Fig. A-1 - Sketch of the cross-correlation function for a dual-tip phase-detection intrusive probe

The shape of the cross-correlation function provides some information on the turbulent velocity fluctuations. Flat cross-correlation functions are associated with large velocity fluctuations around the mean and large turbulence intensity. Thin high cross-correlation curves are characteristics of small turbulent velocity fluctuations. The information must be corrected to account for the intrinsic noise of the leading probe signal and the turbulence intensity is related to the broadening of the cross-correlation function compared to the autocorrelation function.
The definition of the standard deviation of the velocity leads to :

$$
\begin{equation*}
\mathrm{u}^{\prime 2}=\frac{\mathrm{V}^{2}}{\mathrm{~N}} \sum_{\mathrm{i}=1}^{\mathrm{N}} \frac{1}{\tau^{2}} *(\tau-\mathrm{T})^{2} \tag{A-2}
\end{equation*}
$$

where V is the mean velocity, N is the number of samples and $\tau$ is the bubble travel time data. With an infinitely large number of data points N , an extension of the mean value theorem for definite integrals may be used as the functions $1 / \tau^{2}$ and $(\tau-T)^{2}$ are positive and continuous over the interval ( $\mathrm{i}=1, \mathrm{~N}$ ) (SPIEGEL 1974). The mean value theorem implies that there exists at least one characteristic bubble travel time $\tau^{\prime}$ satisfying $\tau_{1} \leq \tau^{\prime} \leq \tau_{\mathrm{N}}$ such that:

$$
\begin{equation*}
\left(\frac{\mathrm{u}^{\prime}}{\mathrm{V}}\right)^{2}=\frac{1}{\mathrm{~N}} * \frac{1}{\tau^{\prime 2}} * \sum_{\mathrm{i}=1}^{\mathrm{N}}(\tau-\mathrm{T})^{2} \tag{A-3}
\end{equation*}
$$

The standard deviation of the velocity is basically proportional to the standard deviation of the bubble travel time:

$$
\begin{equation*}
\frac{\mathrm{u}^{\prime}}{\mathrm{V}}=\frac{\sigma_{\tau}}{\tau^{\prime}} \tag{A-4}
\end{equation*}
$$

Assuming that the successive detections of bubbles by the probe sensors is a true random process (e.g. affected only by random advective dispersion of the bubbles and random velocity fluctuations over the distance separating the probe sensors), the cross-correlation function is a Gaussian distribution :

$$
\begin{equation*}
\mathrm{R}_{\mathrm{xy}}(\tau)=\mathrm{R}_{\max } * \exp \left(-\left(\frac{\tau-\mathrm{T}}{\sigma_{\mathrm{T}}}\right)^{2}\right) \tag{A-5}
\end{equation*}
$$

where $\sigma_{\mathrm{T}}$ is the standard deviation of the cross-correlation function. Defining $\Delta \mathrm{T}$ as a time scale satisfying : $\mathrm{R}_{\mathrm{xy}}(\mathrm{T}+\Delta \mathrm{T})=\mathrm{R}_{\max } / 2$, the standard deviation equals : $\sigma_{\mathrm{T}}=\Delta \mathrm{T} / 1.175$ for a true Gaussian distribution. The standard deviation of the bubble travel time $\sigma_{\tau}$ is a function of both the standard deviations of the cross-correlation and autocorrelation functions :

$$
\sigma_{\tau}=\frac{\sqrt{\Delta \mathrm{T}^{2}-\Delta \mathrm{t}^{2}}}{1.175}
$$

where $\Delta \mathrm{t}$ is the characteristic time for which the normalised autocorrelation function equals 0.5 . Assuming that $\tau^{\prime} \sim \mathrm{T}$ and that the bubble/droplet travel distance is a constant $\Delta \mathrm{x}$, Equation (A-4) implies that the turbulence intensity $\mathrm{u}^{\prime} / \mathrm{V}$ equals :

$$
\begin{equation*}
\mathrm{Tu}=\frac{\mathrm{u}^{\prime}}{\mathrm{V}} \approx 0.851 * \frac{\sqrt{\Delta \mathrm{~T}^{2}-\Delta \mathrm{t}^{2}}}{\mathrm{~T}} \tag{A-7}
\end{equation*}
$$

Tu is a dimensionless velocity scale that is characteristic of the turbulent velocity fluctuations over the distance $\Delta \mathrm{x}$ separating the probe sensors. Although Tu is not strictly equal to the dimensionless turbulent velocity fluctuation, it provides some information on the turbulence level in air-water flows.

## DISCUSSION: EFFECT OF THE DUAL-TIP PROBE DESIGN

Hubert CHANSON's experience in air-water flows suggested that the standard deviation of the bubble travel time could also be a function of the distance $\Delta x$ between sensors. For a given bubbly flow configuration and probe sensors, the cross-correlation function broaden and the maximum cross-correlation decreases with increasing distance $\triangle x$. KIPPHAN (1977) recommended an optimum distance $\Delta \mathrm{x}$ between sensor equal to :

$$
\begin{equation*}
\frac{(\Delta \mathrm{x})_{\mathrm{opt}}}{\delta \mathrm{x}} \approx \frac{0.35}{\mathrm{Tu}} \tag{A-8}
\end{equation*}
$$

where $\delta \mathrm{x}$ is the characteristic sensor size in the flow direction. Equation (A-8) does not account however for the characteristic size of the two-phase flow structure.
CHANSON and TOOMBES (2001a) reviewed a number of successful designs of dual-tip resistivity and optical fibre probes. Based upon these designs and their successful operation, CHANSON and TOOMBES proposed an "optimum" probe spacing :

$$
\frac{(\Delta \mathrm{x})_{\mathrm{opt}}}{\delta \mathrm{x}}=33.5 * \mathrm{~V}_{\max } 0.27(\mathrm{~A}-9)
$$

where $\mathrm{V}_{\text {max }}$ is the maximum bubbly flow velocity in $\mathrm{m} / \mathrm{s}$. Equation (A-9) is based upon laboratory and prototype studies conducted with $0.4 \leq \mathrm{V}_{\max } \leq 18.5 \mathrm{~m} / \mathrm{s}$ and $1.5 \leq \Delta \mathrm{x} \leq 102 \mathrm{~mm}$. During the present study, the streamwise distance between probe sensors was $\Delta x=7.74 \mathrm{~mm}$, and the characteristic sensor size in the flow direction was about : $\delta x=0.025$ to 0.05 mm .
The velocity and turbulent velocity fluctuation calculations may be further affected by any offset between the leading and trailing tips of the probe. For example, CHANSON (1995b, 1997) introduced successfully such an offset to reduce the effects of separation and wake downstream of the leading tip reported by SENE (1984) and CHANSON (1988). The probe design is sketched in Figure A-2. With this design, CUMMINGS (1996) studied the effects of trailing probe offset $\Delta \mathrm{z}$. His tests indicated that, for $\Delta \mathrm{x}=8 \mathrm{~mm}$, a lateral displacement of 0.43 mm experienced some wake problems similar to those observed by SENE (1984) and CHANSON (1988). He tested further $\Delta \mathrm{z}=$ $0.58 \mathrm{~mm}, 1.33 \mathrm{~mm}$ and 1.57 mm , which all performed satisfactorily, although the 0.58 mm lateral offset gave the "best performance" (CUMMINGS 1996). In the present study, the lateral offset was $\Delta z=0.472 \mathrm{~mm}$ while $\Delta x=7.74 \mathrm{~mm}$. No wake problem was experienced.

## APPENDIX B - HYDRAULIC ROUGHNESS OF THE SCREENS

The hydraulic roughness of the screens was tested in a 20 m long, 0.25 m wide tilting flume with glass walls at the University of Queensland Gordon McKAY Hydraulics Laboratory. For a 10 m length, the channel bed was covered with the rough screen pattern (Fig. B-1). (The sidewalls were made of glass.) The gradually-varied free-surface profile was recorded in the fully-developed flow region for a range of flow rates ( 0.017 to $0.04 \mathrm{~m}^{3} / \mathrm{s}$ ) and bed slopes ( $\mathrm{S}_{\mathrm{O}}=0.09$ to 0.15 ). Visually the water depth was significantly larger over the rough invert than with a glass bottom, demonstrating the enhanced flow resistance. This is illustrated in Figure B-1B showing the flow at the downstream end of the screen bed section, with a rapid drop in surface elevation once the waters flow over the smooth glass bottom.
For each run, the average boundary shear stress $\tau_{\mathrm{o}}$ was calculated from the friction slope $\mathrm{S}_{\mathrm{f}}$ which satisfied the differential form of the energy equation :

$$
\begin{equation*}
\frac{\partial \mathrm{H}}{\partial \mathrm{~s}}=-\mathrm{S}_{\mathrm{f}} \tag{B-1}
\end{equation*}
$$

where H is the total head and s is the streamwise coordinate. The friction slope was related to the overall boundary shear stress $\tau_{\mathrm{O}}$ :

$$
\begin{equation*}
\mathrm{S}_{\mathrm{f}}=\frac{4^{*} \tau_{\mathrm{o}}}{\rho^{*} \mathrm{~g}^{*} \mathrm{D}_{\mathrm{H}}} \tag{B-2}
\end{equation*}
$$

where $\rho$ is the fluid density, $g$ is the gravity acceleration and $\mathrm{D}_{\mathrm{H}}$ is the hydraulic diameter.
The bed shear stress $\tau_{\text {screen }}$ was deduced as :

$$
\begin{equation*}
\tau_{\mathrm{o}} *(\mathrm{~W}+2 * \mathrm{~d})=\tau_{\text {screen }} * \mathrm{~W}+\tau_{\mathrm{wall}} * 2 * \mathrm{~d} \tag{B-3}
\end{equation*}
$$

where W is the channel width, d is the water depth and $\tau_{\text {wall }}$ is the glass sidewall shear stress which was deduced from the Moody diagram assuming an equivalent roughness height $\mathrm{k}_{\mathrm{S}}=0.1 \mathrm{~mm}$ (IDELCHIK 1969,1986,1994, HENDERSON 1966, CHANSON 2004a). The results in terms of the Darcy friction factors for the screens are reported in Table B-1 (column 7). For the tests, the equivalent Darcy friction factor of the screens ranged from $f_{\text {screen }}=0.05$ to 0.08 , corresponding to a Gauckler-Manning coefficient of about 0.016 to $0.02 \mathrm{~s} / \mathrm{m}^{1 / 3}$.
The dimensionless screen shear stress results are compared with the Colebrook-White formula in Figure B-2A. The correlation is poor but the Colebrook-White formula is not truly applicable to present roughness elements. Indeed the screens are porous and the induced flow resistance is a combination of skin friction and form drag. The best correlation with the Colebrook-White formula was achieved for an equivalent sand roughness height $\mathrm{k}_{\mathrm{S}}{ }^{\prime}=6.6 \mathrm{~mm}$ that is comparable to the screen thickness $\mathrm{k}=8 \mathrm{~mm}$.
Overall the flow conditions were fully-rough turbulent and the results were basically independent of Reynolds number. The data were best correlated by :

$$
\begin{equation*}
\frac{1}{\sqrt{\mathrm{f}_{\text {screen }}}}=0.252 *\left(\frac{\mathrm{k}}{\mathrm{D}_{\mathrm{H}}}\right)^{-0.823} \tag{B-4}
\end{equation*}
$$

with a normalised correlation coefficient of 0.783 , where k is the screen height $(\mathrm{k}=8 \mathrm{~mm})$. Equation (B-4) is shown in Figure B-2B and compared with the experimental results.

Table B-1 - Experimental results

## APPENDIX C - INCEPTION OF AIR ENTRAINMENT

Skimming flows cascading down stepped spillways exhibit an appearance similar to self-aerated flows down a smooth chute invert (Fig. C-1). The upstream end has a smooth and transparent look characteristic of clear-water flow. However next to the upstream chute inlet a boundary layer develops. When the outer edge of the boundary layer reaches the free surface, the turbulence induces natural aeration. This point is called the point of inception of air entrainment.
In the developing boundary layer region, the velocity distribution follows closely a power law given by:

$$
\begin{equation*}
\frac{\mathrm{V}}{\mathrm{~V}_{\max }}=\left(\frac{\mathrm{y}}{\delta_{\mathrm{BL}}}\right)^{\frac{1}{\mathrm{~N}}} \text { for } 0<\frac{\mathrm{y}}{\delta}<1 \tag{C-1}
\end{equation*}
$$

where $\delta_{\mathrm{BL}}$ is the boundary layer thickness, y is the distance normal to the pseudo-bottom and $\mathrm{V}_{\text {max }}$ is the ideal fluid velocity, deduced from the Bernoulli equation as:

$$
\begin{equation*}
\mathrm{V}_{\max }=\sqrt{2 \mathrm{~g}\left(\mathrm{H}_{\max }-\mathrm{d} \cdot \cos \theta\right)} \tag{C-2}
\end{equation*}
$$

where $\mathrm{H}_{\text {max }}$ is the upstream total head, $\theta$ is the channel slope and d the flow depth .
CHANSON (1995a) re-analysed the flow properties for a wide range of model data (e.g. BEITZ and LAWLESS 1992, BINDO et al. 1993, FRIZELL and MEFFORD 1991, SORENSEN 1985, TOZZI 1992) to predict the growth of the boundary layer and to locate the point of inception.
The best data fit is given by:

$$
\begin{align*}
& \frac{L_{I}}{\mathrm{~h} \cdot \cos \theta}=9.719 \cdot(\sin \theta)^{0.713} \cdot\left(\mathrm{~F}_{*}\right)^{0.713}  \tag{C-3}\\
& \frac{\mathrm{~d}_{\mathrm{I}}}{\mathrm{~h} \cdot \cos \theta}=\frac{0.4034}{(\sin \theta)^{0.04}} \cdot(\mathrm{~F} *)^{0.592} \tag{C-4}
\end{align*}
$$

where $L_{I}$ and $d_{I}$ are the length to, and depth at, the point of inception, $\theta$ is is the channel slope, $k_{s}=$ $\mathrm{h}^{*} \cos \theta$ is the roughness height measured perpendicular to the flow direction and $\mathrm{F} *$ is the Froude number defined in terms of the roughness height calculated as:

$$
\begin{equation*}
\mathrm{F}_{v}=\frac{\mathrm{q}_{\mathrm{w}}}{\sqrt{\mathrm{~g} \cdot \sin \theta \cdot \mathrm{k}_{\mathrm{s}}^{3}}} \tag{C-5}
\end{equation*}
$$

where $\mathrm{q}_{\mathrm{w}}$ is the water discharge per unit width
Fig. C-1 - Location of the inception point

The position of the inception point is function of both water discharge and step roughness. For a given channel geometry, the location of the point of inception moves downstream with increasing discharges.
In this study, it was observed that the location of the inception point changed with the step roughness for larger relative discharges ( $\mathrm{d}_{\mathcal{C}} \mathrm{h}=1.4 \& 1.5$ ). Such position shifted downstream for rough step faced spillways. A comparison of inception point positions for the three tested rough step faced configurations (Config. A, B \&C) with smooth faced stepped chutes is shown in Table $\mathrm{C}-1$ and Fig. C-2. The results indicate that the inception point position for rough step face spillways was approximately $35 \%$ larger than that on smooth step faced chutes.
For this study, the data corresponding to the rough step faced configurations was best correlated by:

$$
\begin{equation*}
\frac{\mathrm{L}_{\mathrm{I}}}{\mathrm{~h} \cdot \cos \theta}=9.51+10.51 \cdot \ln \left(\mathrm{~F}_{*}\right) \tag{C-6}
\end{equation*}
$$

while data corresponding to the smooth step chute was best fitted by:

$$
\begin{equation*}
\frac{\mathrm{L}_{\mathrm{I}}}{\mathrm{~h} \cdot \cos \theta}=10.3+2.05 \cdot \mathrm{~F}_{*} \tag{C-7}
\end{equation*}
$$

where $L_{I}$ is the length to the point of inception, $\theta$ is is the channel slope, and $\mathrm{F} *$ is the Froude number. A comparison of model and prototype data obtained by several authors is shown in Figure C-3 as reference

Table C-1 - Positions of the inception point for spillways with smooth and rough step faces ( $\theta=$ $21.8^{\circ}, \mathrm{h}=0.1 \mathrm{~m}$ )

|  |  | Point of inception location $\left(\mathrm{L}_{\mathrm{I}}\right)$ |  |  |  |
| :---: | :---: | :--- | :--- | :--- | :--- |

## APPENDIX D - AIR-WATER FLOW PROPERTIES

Four water discharges ranging from 0.114 to $0.219 \mathrm{~m}^{3} / \mathrm{s}$ in skimming flow regime were investigated for each of the four channel configurations (Smooth and rough step faced chutes). Table D-1 summarises the investigated conditions.
Measurements were conducted with a double-tip conductivity probe located on the channel centreline at step edges and at dimensionless distances $\mathrm{X}_{0}=0.25,0.5$ and 0.75 between step edges where $\mathrm{X}_{0}=\mathrm{x} / \mathrm{L}_{\text {cav }}, \mathrm{x}$ is the distance to the upper step edge and $\mathrm{L}_{\text {cav }}$ is the distance between step edges $\left(L_{c a v}=\sqrt{h^{2}+1^{2}}\right.$; Fig. D-1). Basic experimental double tip conductivity probe results comprised void fraction C , air-water flow velocity V , bubble count rate F , turbulence intensity Tu , noise $\xi{ }^{(1)}$ and bubble chord size distributions.
Detailed experimental air-water flow properties distributions measured normally to the flow for all investigated discharges and locations are presented in Table D-2, where y is the measurement depth, C is the void fraction, V is the air-water flow velocity, F is the bubble count rate, Tu is the turbulence intensity and $\xi$ is the noise defined as $\xi=0.851 \cdot \Delta \mathrm{t} / \mathrm{T}$, where $\Delta \mathrm{t}$ is the characteristic time for which the normalised autocorrelation function equals 0.5 and T is the average interface travel time for which the cross-correlation function is maximum (Appendix A).

## APPENDIX E - DEPTH AVERAGED AIR-WATER FLOW PROPERTIES

Depth averaged air-water flow properties corresponding to measurements conducted at step edges are presented in Table E-1 and Figure E-1. Basic results include dimensionless maximum bubble count rate $F_{\text {max }} \cdot d_{d} / V_{c}$, depth averaged air content $C_{\text {mean }}$, dimensionless depth $Y_{90} / d_{c}$ for $C=0.90$, dimensionless air-water flow velocity $\mathrm{V}_{90} / \mathrm{V}_{\mathrm{c}}$ at $\mathrm{y}=\mathrm{Y}_{90}$, dimensionless mean flow velocity $\mathrm{U}_{\mathrm{w}} / \mathrm{V}_{\mathrm{c}}$ and equivalent clear water depth $d$ where $d_{c}$ is the critical depth and $V_{c}$ is the critical velocity. The depth averaged concentration $\mathrm{C}_{\text {mean }}$ is defined as:

$$
\begin{equation*}
\mathrm{C}_{\text {mean }}=\int_{0}^{\mathrm{Y}_{00}} \mathrm{C} \cdot \mathrm{dy} \tag{E-1}
\end{equation*}
$$

where $y$ is measured normal to the pseudo-bottom formed by the step edges and $\mathrm{Y}_{90}$ is the depth corresponding to $\mathrm{C}=0.90$. The equivalent clear water depth, d is defined as:

$$
\begin{equation*}
d=\int_{0}^{Y_{90}}(1-C) \cdot d y=\left(1-C_{\text {mean }}\right) \cdot Y_{90} \tag{E-2}
\end{equation*}
$$

The mean flow velocity $\mathrm{U}_{\mathrm{w}}$ is calculated as:

$$
\begin{equation*}
\mathrm{U}_{\mathrm{w}}=\frac{\mathrm{q}_{\mathrm{w}}}{\mathrm{~d}} \tag{E-3}
\end{equation*}
$$

where $\mathrm{q}_{\mathrm{w}}$ is the water discharge per unit width.

## BIBLIOGRAPHIC REFERENCE OF THE RESEARCH REPORT CE160

The Civil Engineering Research Report series CE is a refereed publication published by the Department of Civil Engineering at the University of Queensland, Brisbane, Australia.

The bibliographic reference of the present report is :
GONZALEZ, C.A., TAKAHASHI, M., and CHANSON, H. (2005). "Effects of Step Roughness in Skimming Flows: an Experimental Study." Research Report No. CE160, Dept. of Civil Engineering, The University of Queensland, Brisbane, Australia, July (ISBN 1864998105).

The Research Report CE160 is available, in the present form, as a series of .PDF files on the Internet at the following address :

> http://www.uq.edu.au/~e2hchans/reprints/ce160.zip

The zip file contains the following files:

| 00_step.pdf | Cover pages |
| :--- | :--- |
| 01_step.pdf | Title page, abstract, table of contents, list of symbols |
| 1_step.pdf | Chap. 1. Introduction <br> 3_step.pdf <br> 7_step.pdf |
| Chap. 2. Experimental setup <br> Chap. 3. Basic flow patterns <br> Chap. 4. Air-water flow properties <br> Chap. 5. Air-water chord properties <br> Chap. 6. Discussion <br> Chap. 7. Summary and conclusion <br> Acknowledgments |  |
| a_step.pdf <br> c_step.pdf <br> f_step.pdf | Appendices <br> App. A - Turbulent velocity measurements with dual-tip probes in air- <br> water flows <br> App. B - Hydraulic roughness of the screens <br> App. C - Inception of air entrainment <br> App. D - Air-water flow properties <br> App. E - Depth averaged air-water flow properties <br> App. F - Experimental data: bubble and water droplet chord lengths |

## PAYMENT INFORMATION

1- VISA Card

| Name on the card : |  |
| :--- | :--- |
| Visa card number : |  |
| Expiry date : |  |
| Amount : | AUD\$ ........................................ |

2- Cheque/remittance payable to : THE UNIVERSITY OF QUEENSLAND and crossed "Not Negotiable".
N.B. For overseas buyers, cheque payable in Australian Dollars drawn on an office in Australia of a bank operating in Australia, payable to: THE UNIVERSITY OF QUEENSLAND and crossed "Not Negotiable".

[^0]:    ${ }^{2}$ GONZALEZ (2005) performed detailed velocity distribution measurements on the broad-crest for a range of flow rates. Measurements were conducted in clear-water flows with a Prandtl-Pitot tube $(\varnothing=3.3 \mathrm{~mm})$. Present discharge estimates are based upon the re-analysis of his results.

[^1]:    ${ }^{1}$ With both smooth and rough step configurations, the location of the inception point was always further upstream than that for a smooth-invert chute flow with the same flow rate and bed slope.

[^2]:    ${ }^{2}$ That is, photography (HOYT and TAYLOR 1996,1997), infra-red sensors (AUGIER 1996) and video-observations (WU and FAETH 1995, WU et al. 1995).

[^3]:    ${ }^{3}$ That is, the total energy per unit mass.
